
Chapter 4

The Processor: B

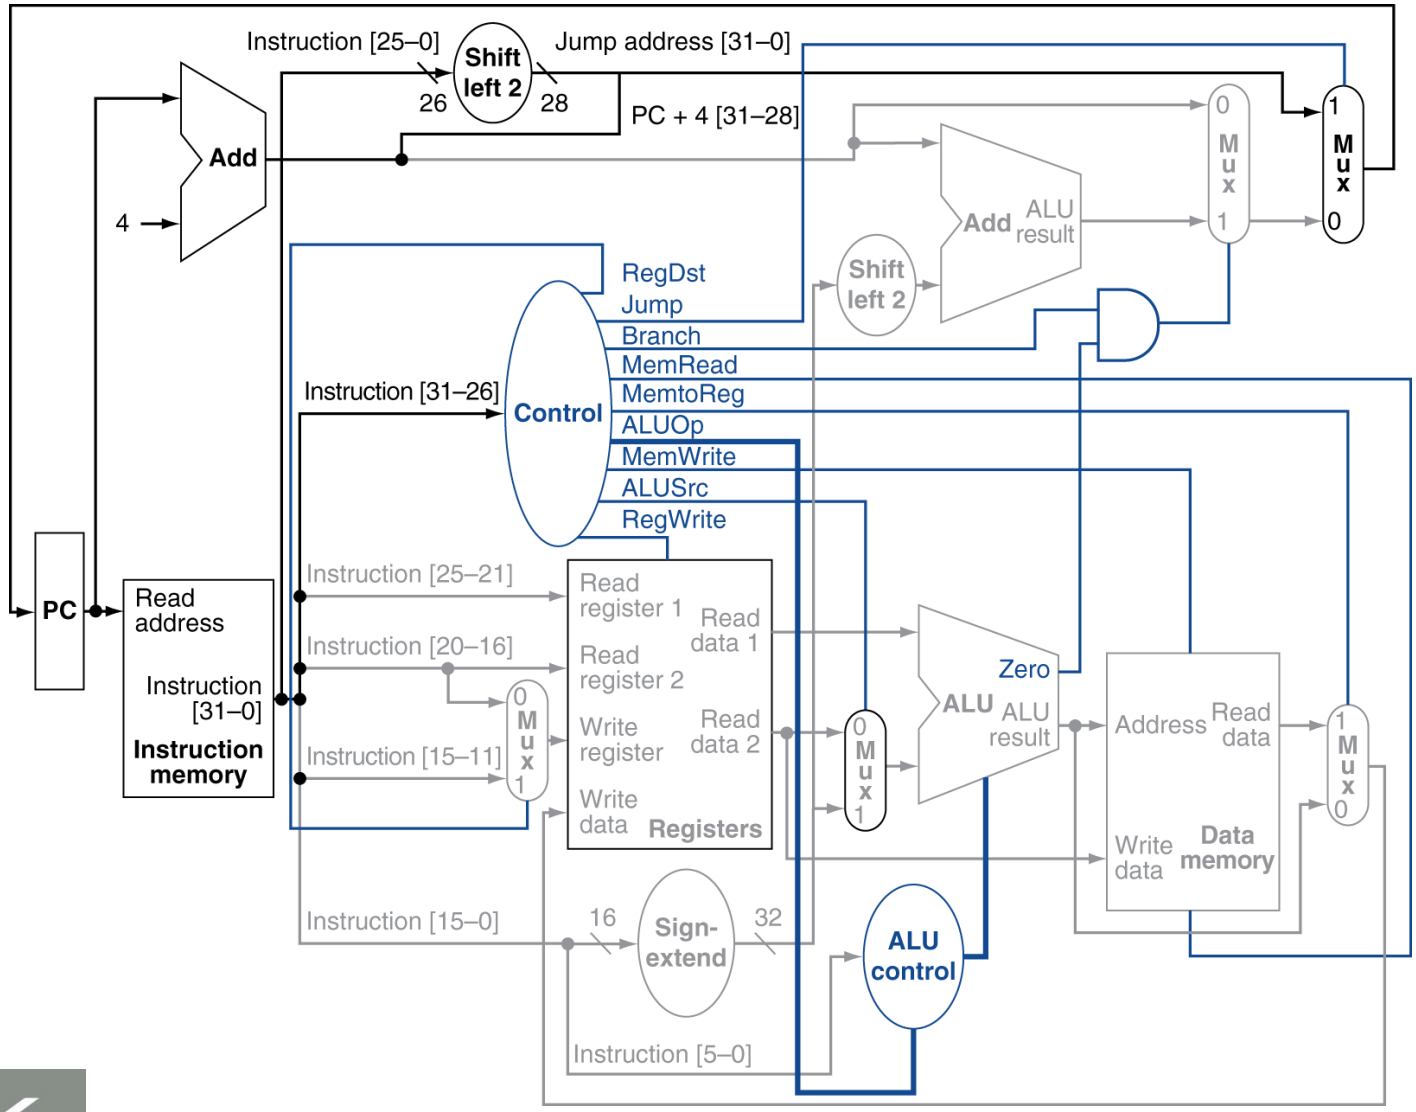
Pipelining

Based on P&H

Term Project

- Deadlines
  - Proposal Mon. March 27,
  - Progress report Wed. April 13,
  - Slides Wed. April 26,
  - Final report Wed. May 3.
- Sources of information: Journals, Conferences, Research Reports, News/Blogs
  - IEEE Explore, ACM Dig Lib, Science Direct
  - Google scholar: backward, forward searches
- Evaluation: Interest/timeliness, extent of research (finding/connecting/extrapolating), presentation (text, non-text)

Datapath With Jumps Added



Performance Issues

- Longest delay determines clock period
  - Critical path: load instruction
  - Instruction memory → register file → ALU → data memory → register file
- Not feasible to vary period for different instructions
- Violates design principle
  - Making the common case fast
- We will improve performance by pipelining

Performance

- Assume time for stages is
  - 100ps for register read or write
  - 200ps for other stages
- Compare pipelined datapath with single-cycle datapath

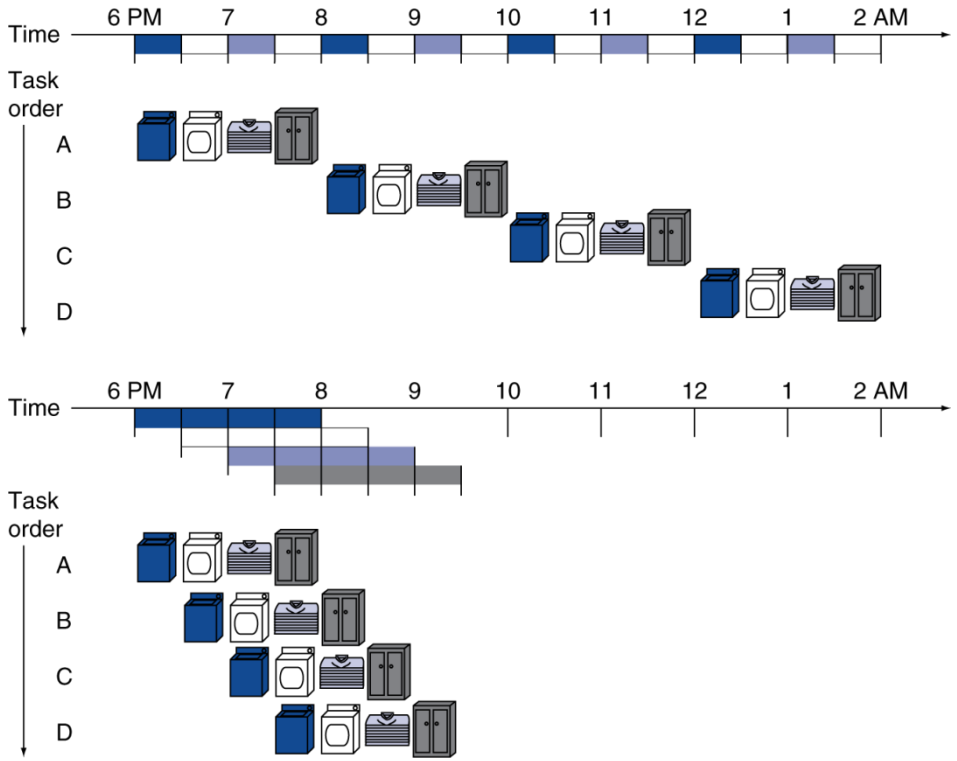
Instr	Instr fetch	Register read	ALU op	Memory access	Register write	Total time
lw	200ps	100 ps	200ps	200ps	100 ps	800ps
sw	200ps	100 ps	200ps	200ps		700ps
R-format	200ps	100 ps	200ps		100 ps	600ps
beq	200ps	100 ps	200ps			500ps

Pipelining

- Instructions flow through the pipeline
  - Works nicely unless things stall in the pipeline
  - https://www.youtube.com/watch?v=8NPzLBSBzPI
  - Pipeline cartoons

Pipelining Analogy

- Pipelined laundry: overlapping execution
  - Parallelism improves performance



- Four loads:
  - Speedup
    = 8 hrs/3.5 hrs = 2.3
- Non-stop (n loads):
  - Speedup
    = 2n/(0.5n + 1.5) ≈ 4
    = number of stages

MIPS Pipeline

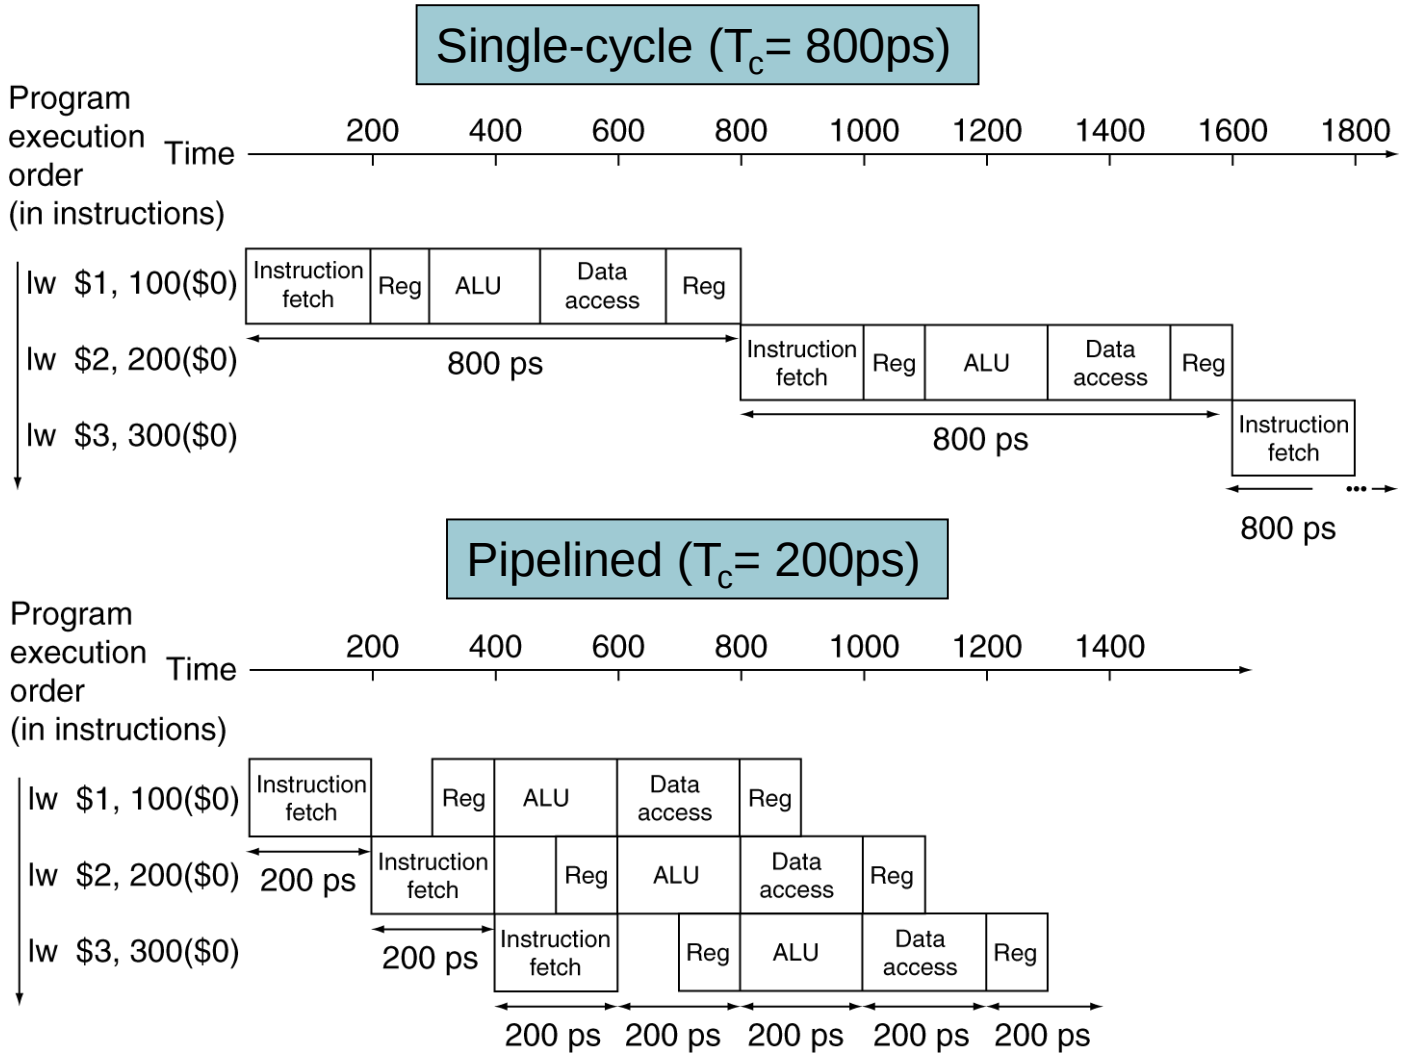
- Five stages, one step per stage
  1. IF: Instruction fetch from memory
  2. ID: Instruction decode & register read
  3. EX: Execute operation or calculate address
  4. MEM: Access memory operand
  5. WB: Write result back to register

Pipeline Performance

- Assume time for stages is
  - 100ps for register read or write
  - 200ps for other stages
- Compare pipelined datapath with single-cycle datapath

Instr	Instr fetch	Register read	ALU op	Memory access	Register write	Total time
lw	200ps	100 ps	200ps	200ps	100 ps	800ps
sw	200ps	100 ps	200ps	200ps		700ps
R-format	200ps	100 ps	200ps		100 ps	600ps
beq	200ps	100 ps	200ps			500ps

Pipeline Performance



Pipeline Speedup

- If all stages are balanced
  - i.e., all take the same time
  - Time between instructions$_{\text{pipelined}}$
    = $\dfrac{\text{Time between instructions}_{\text{nonpipelined}}}{\text{Number of stages}}$
- If not balanced, speedup is less
- Speedup due to increased throughput
  - Latency (time for each instruction) does not decrease

Pipelining and ISA Design

- MIPS ISA designed for pipelining
  - All instructions are 32-bits
    - Easier to fetch and decode in one cycle
    - c.f. x86: 1- to 17-byte instructions
  - Few and regular instruction formats
    - Can decode and read registers in one step
  - Load/store addressing
    - Can calculate address in 3rd stage, access memory in 4th stage
  - Alignment of memory operands
    - Memory access takes only one cycle

Hazards that impact pipelining

- Situations that prevent starting the next instruction in the next cycle
- Structure hazards
  - A required resource is busy
- Data hazard
  - Need to wait for previous instruction to complete its data read/write
- Control hazard
  - Deciding on control action depends on previous instruction

Structure Hazards

- Conflict for use of a resource
- In MIPS pipeline with a single memory
  - Load/store requires data access
  - Instruction fetch would have to *stall* for that cycle
    - Would cause a pipeline “bubble”

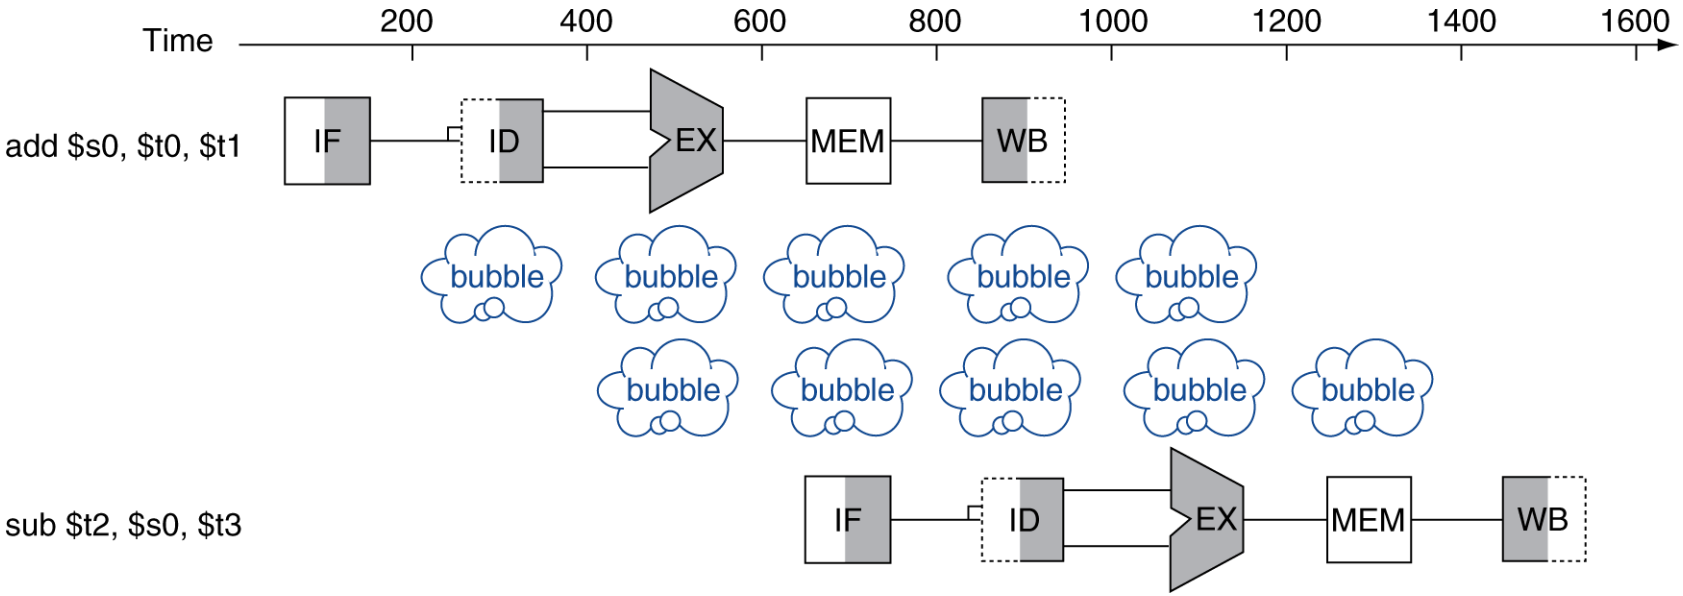
Not a problem in this design, separate instruction memory

- Hence, pipelined datapaths require separate instruction/data memories
  - Or separate instruction/data caches

Data Hazards

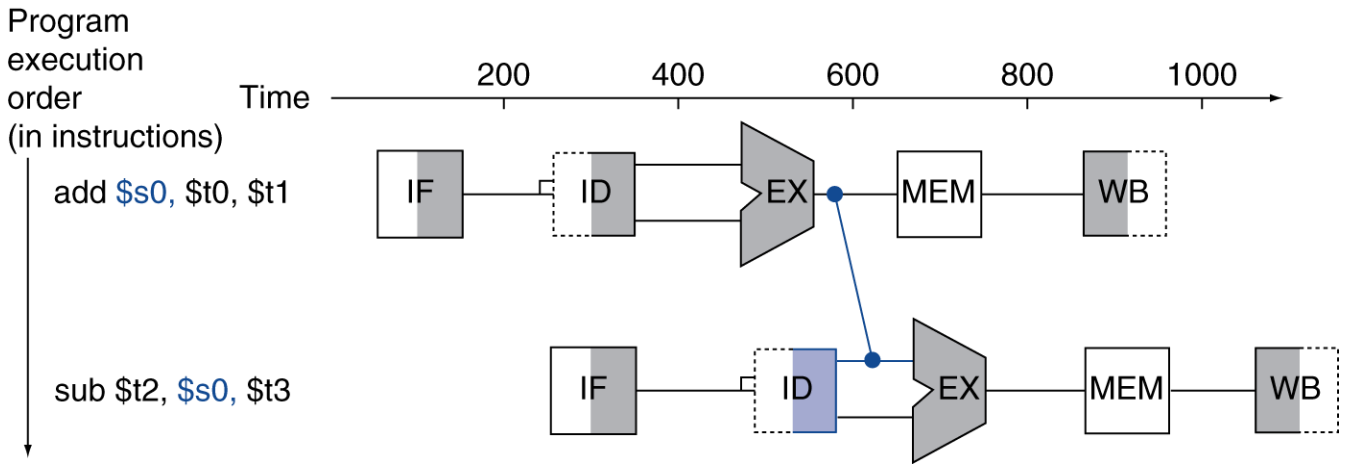
- An instruction depends on completion of data access by a previous instruction
  - `add $s0, $t0, $t1`
    `sub $t2, $s0, $t3`

But Reg Read (ID) must follow WB



Forwarding (aka Bypassing)

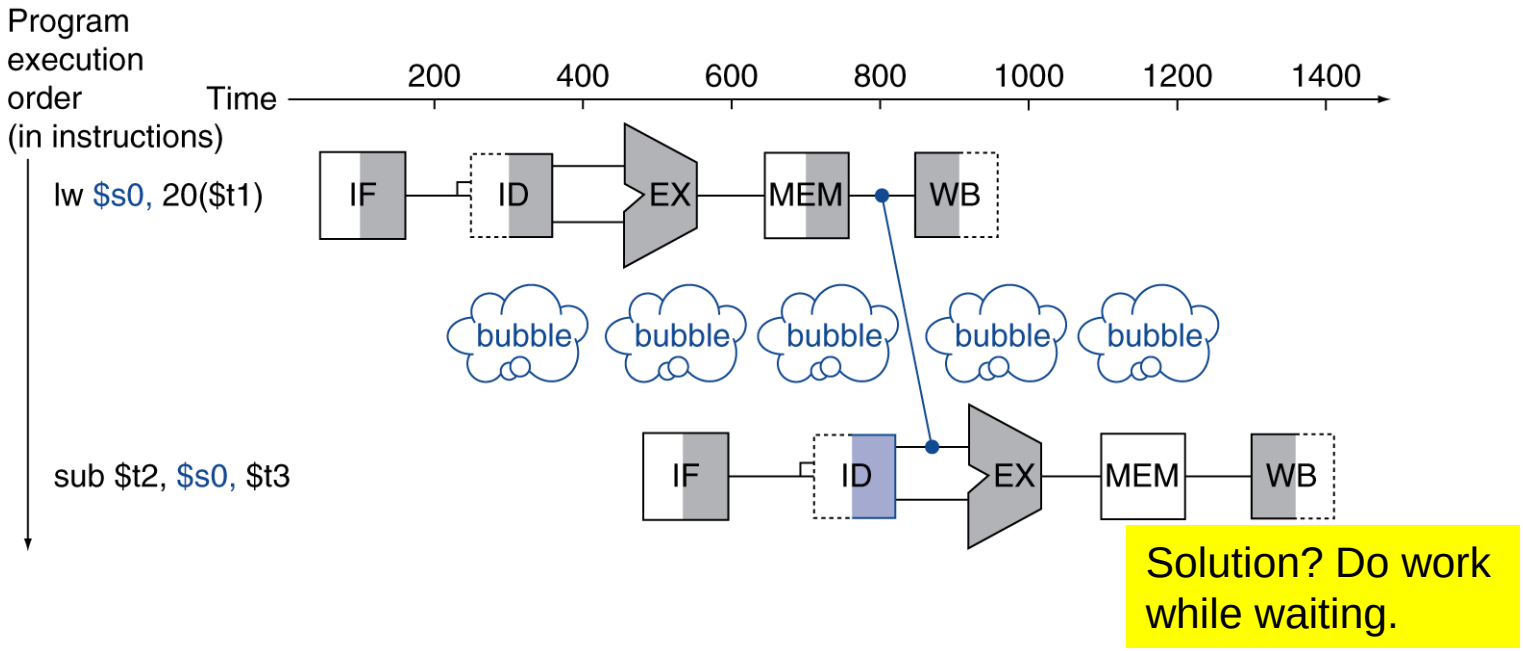
- Use result when it is computed
  - Don’t wait for it to be stored in a register
  - Requires extra connections in the datapath



Implementation details - later

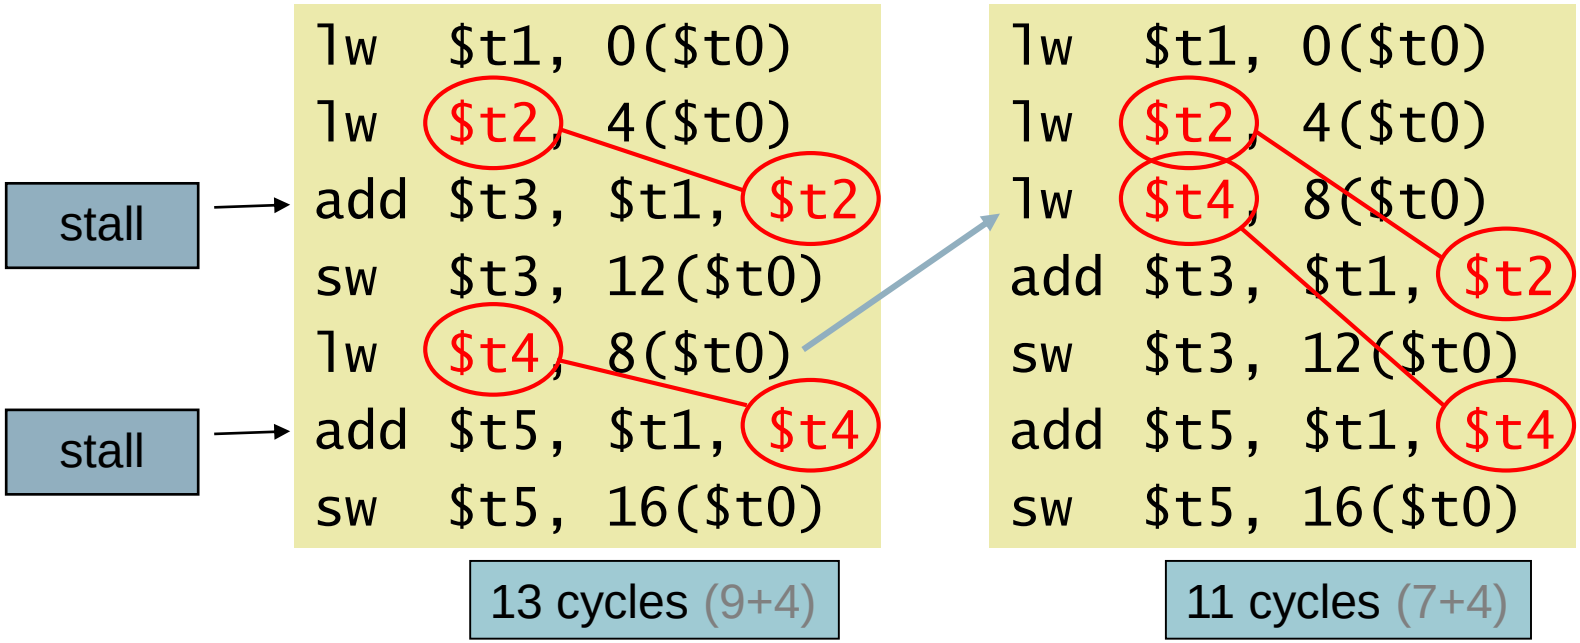
Load-Use Data Hazard

- Can’t always avoid stalls by forwarding
  - If value not computed when needed
  - Can’t forward backward in time!



Code Scheduling to Avoid Stalls

- Reorder code to avoid use of load result in the next instruction
- C code for `A = B + E; C = B + F;`

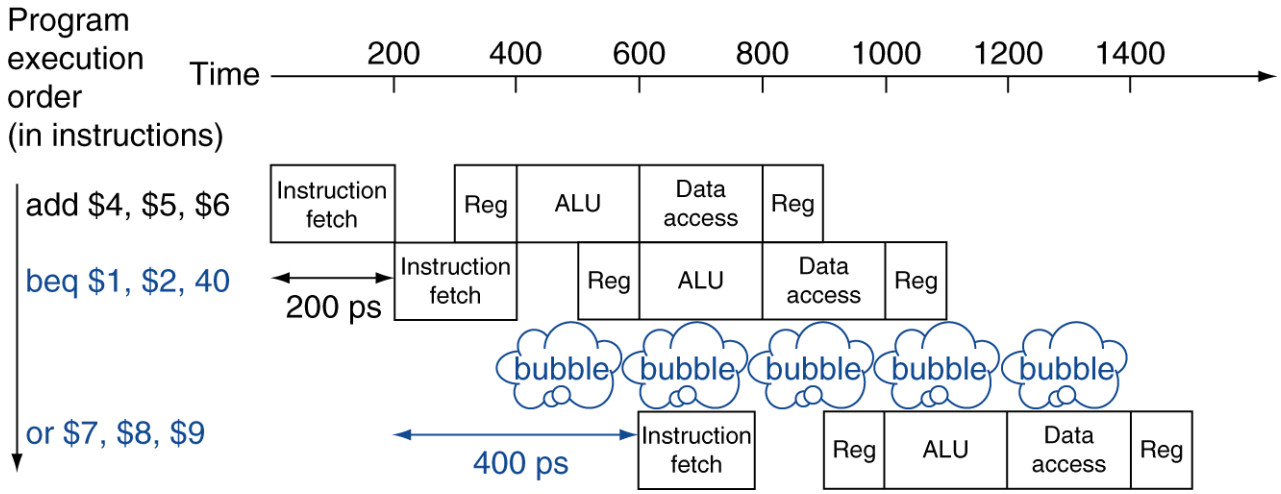


Control Hazards

- Branch determines flow of control
  - Fetching next instruction depends on branch outcome
  - Pipeline can’t always fetch correct instruction
    - Still working on ID stage of branch
- In MIPS pipeline
  - Need to compare registers and compute target early in the pipeline
  - Add hardware to do it in ID stage

Stall on Branch

- Wait until branch outcome determined before fetching next instruction



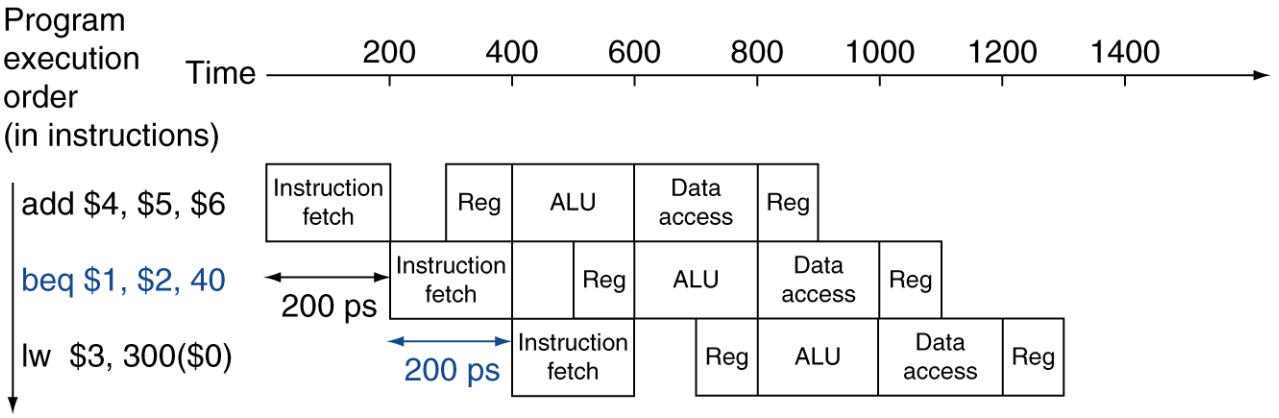
If comparison build into ID stage (Reg Read)

Branch Prediction

- Longer pipelines can't readily determine branch outcome early
  - Stall penalty becomes unacceptable
- Predict outcome of branch
  - Only stall if prediction is wrong
- In MIPS pipeline
  - Can predict branches not taken
  - Fetch instruction after branch, with no delay

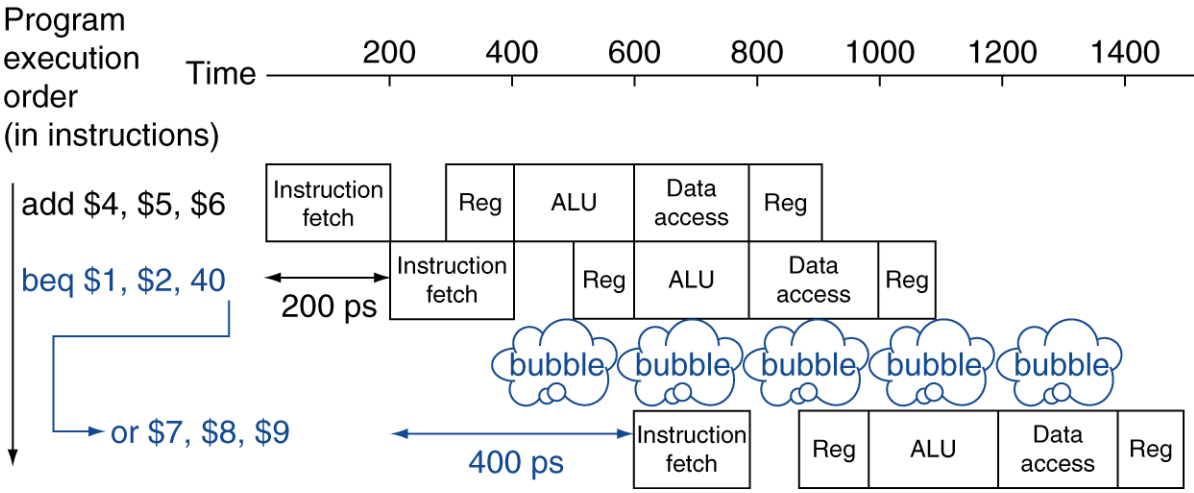
MIPS with Predict Not Taken

Prediction correct



Correctness verified at end of Red read

Prediction incorrect



More-Realistic Branch Prediction

- Static branch prediction
  - Based on typical branch behavior
  - Example: loop and if-statement branches
    - Predict backward branches taken
    - Predict forward branches not taken
- Dynamic branch prediction
  - Hardware measures actual branch behavior
    - e.g., record recent history of each branch
  - Assume future behavior will continue the trend
    - When wrong, stall while re-fetching, and update history

Pipeline Summary

The BIG Picture

- Pipelining improves performance by increasing instruction throughput
  - Executes multiple instructions in parallel
  - Each instruction has the same latency
- Subject to hazards
  - Structure, data, control
- Instruction set design affects complexity of pipeline implementation

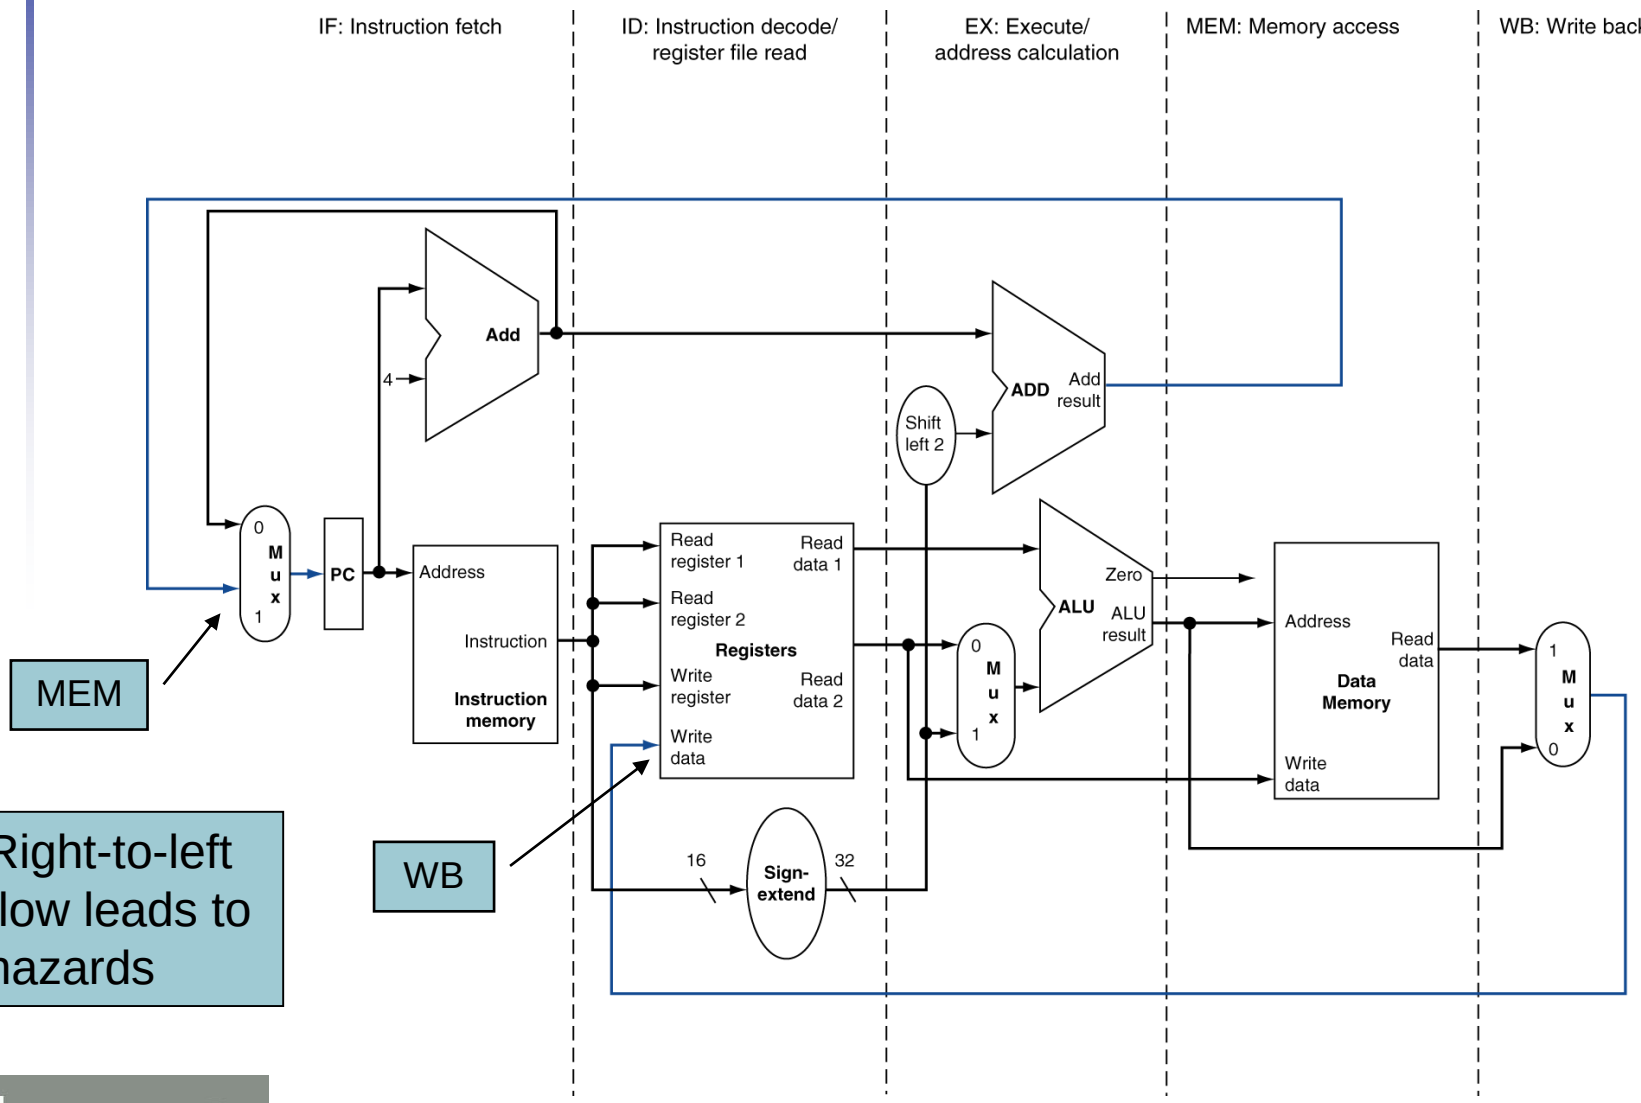
Now the details next

MIPS Pipelined Design Details

- Pipeline registers, stages
- Look for and fix inconsistencies
- Multi-cycle diagrams
- Timing control signals

- Resolving hazards
  - Forwarding
  - Stalling, Branching
  - Branch Prediction

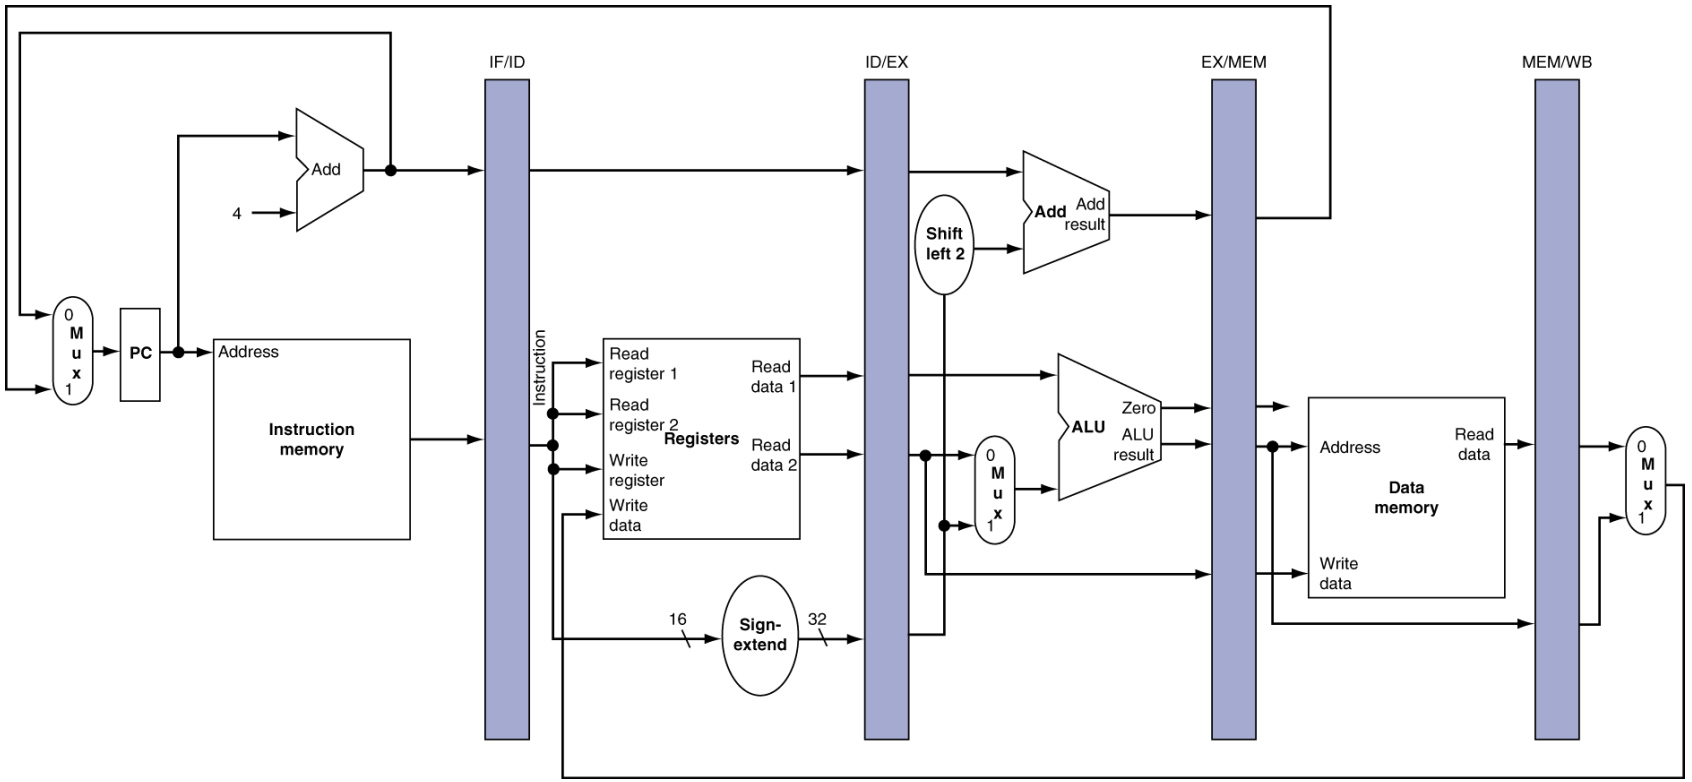
MIPS Pipelined Datapath



Right-to-left flow leads to hazards

Pipeline registers

- Need registers between stages
  - To hold information produced in previous cycle



Pipeline Operation

- Cycle-by-cycle flow of instructions through the pipelined datapath
  - “Single-clock-cycle” pipeline diagram
    - Shows pipeline usage in a single cycle
    - Highlight resources used
  - c.f. “multi-clock-cycle” diagram
    - Graph of operation over time
- We’ll look at “single-clock-cycle” diagrams for load & store

First we will look at data flow, then control

IF for Load, Store, …

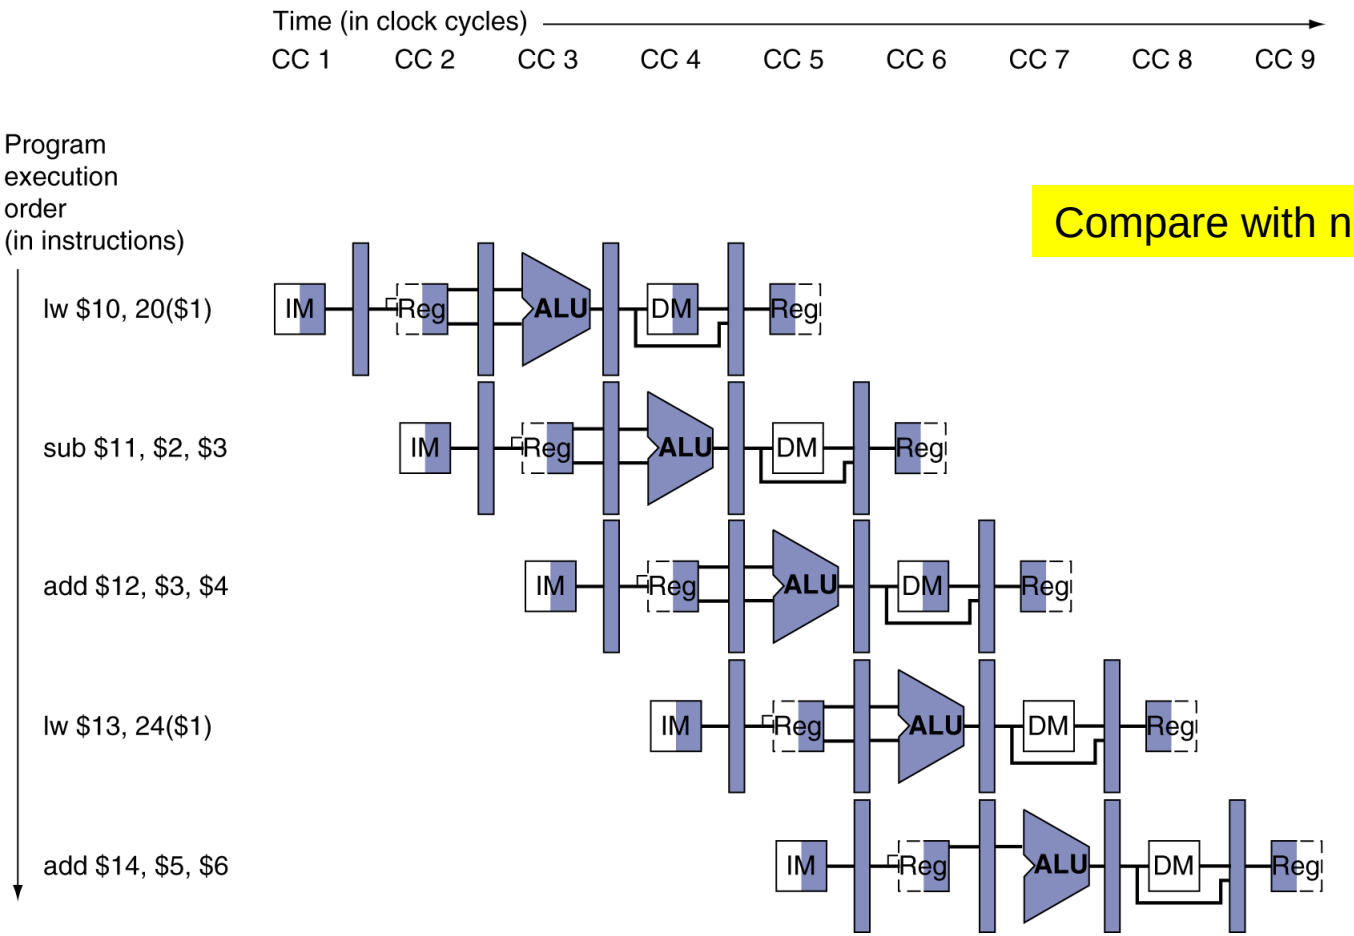
Multi-Cycle Pipeline Diagram

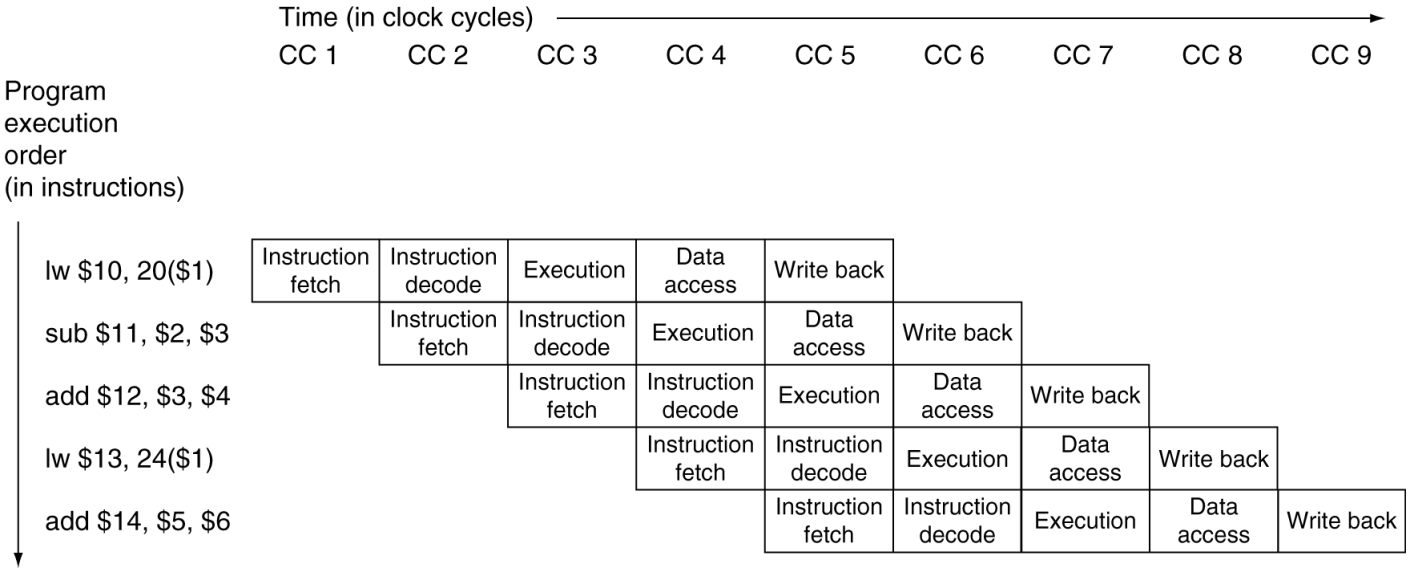
- Form showing resource usage



Compare with next slide

Multi-Cycle Pipeline Diagram

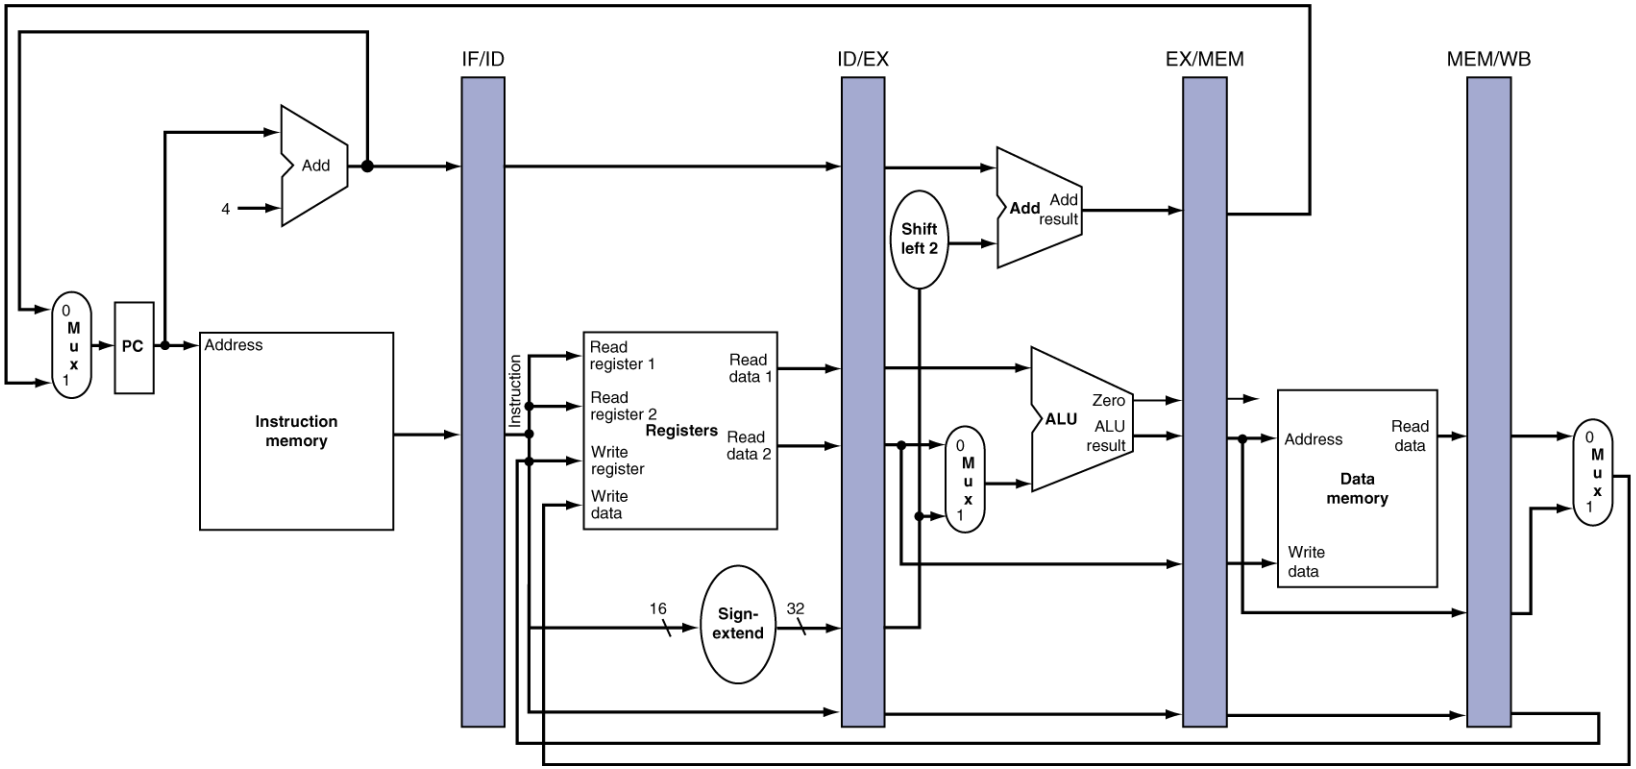
- Traditional form



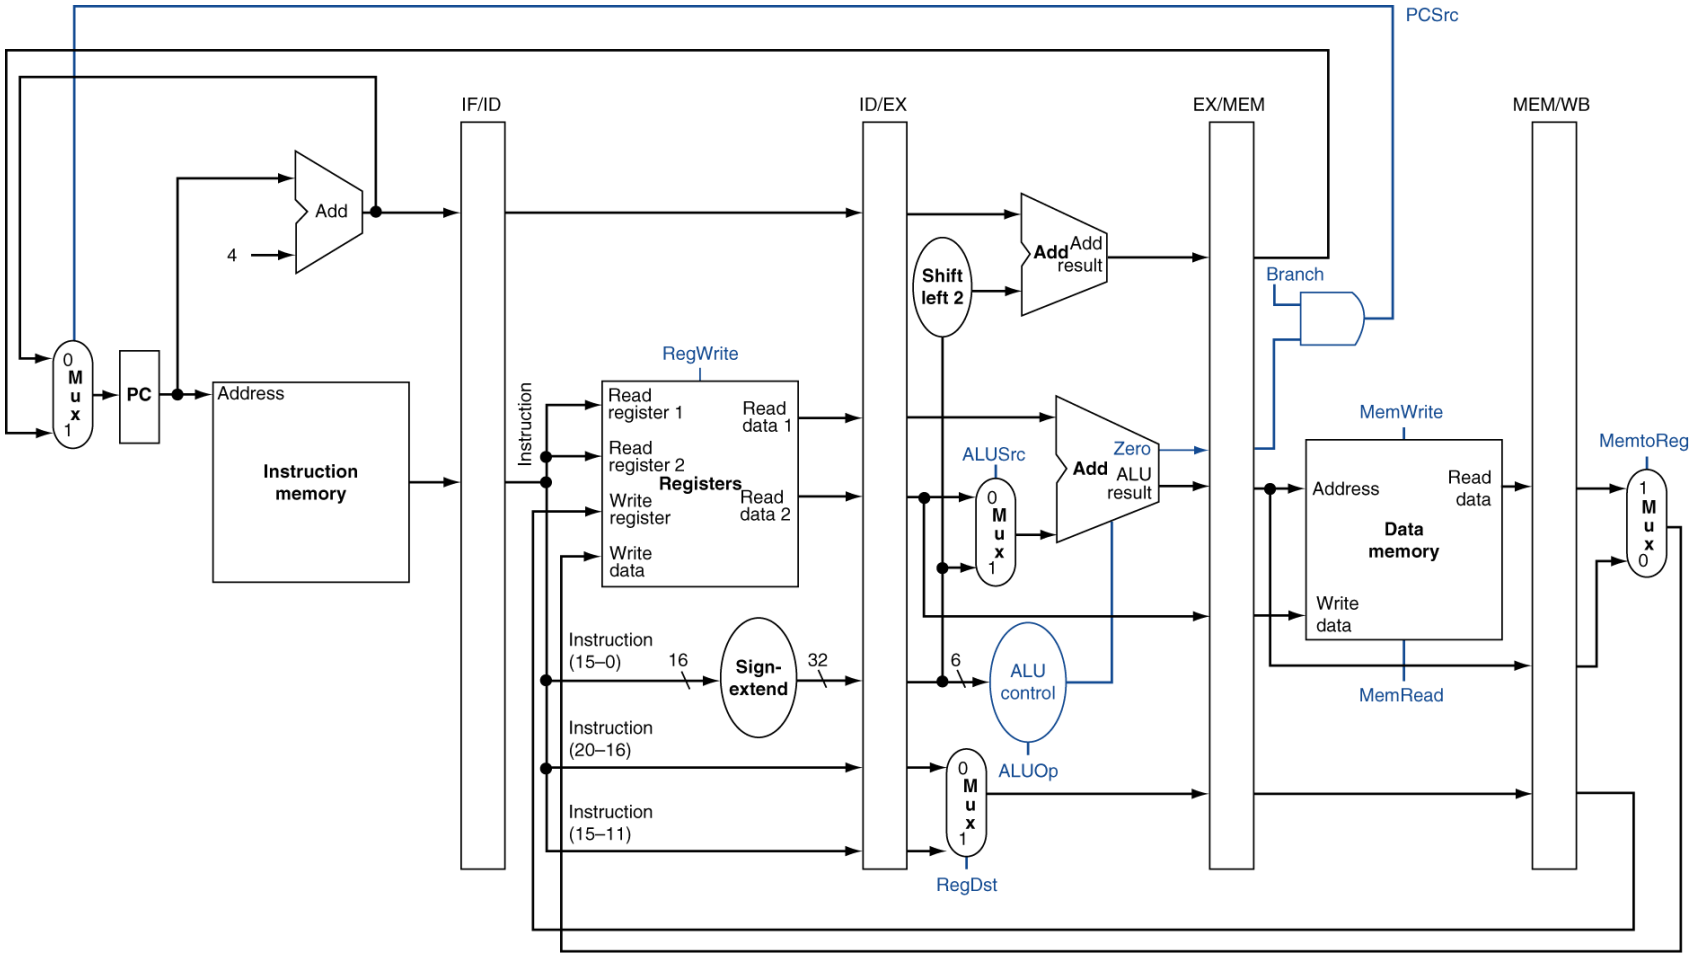
Single-Cycle Pipeline Diagram

- State of pipeline in a given cycle

add $14, $5, $6	lw $13, 24 ($1)	add $12, $3, $4	sub $11, $2, $3	lw $10, 20($1)
Instruction fetch	Instruction decode	Execution	Memory	Write-back



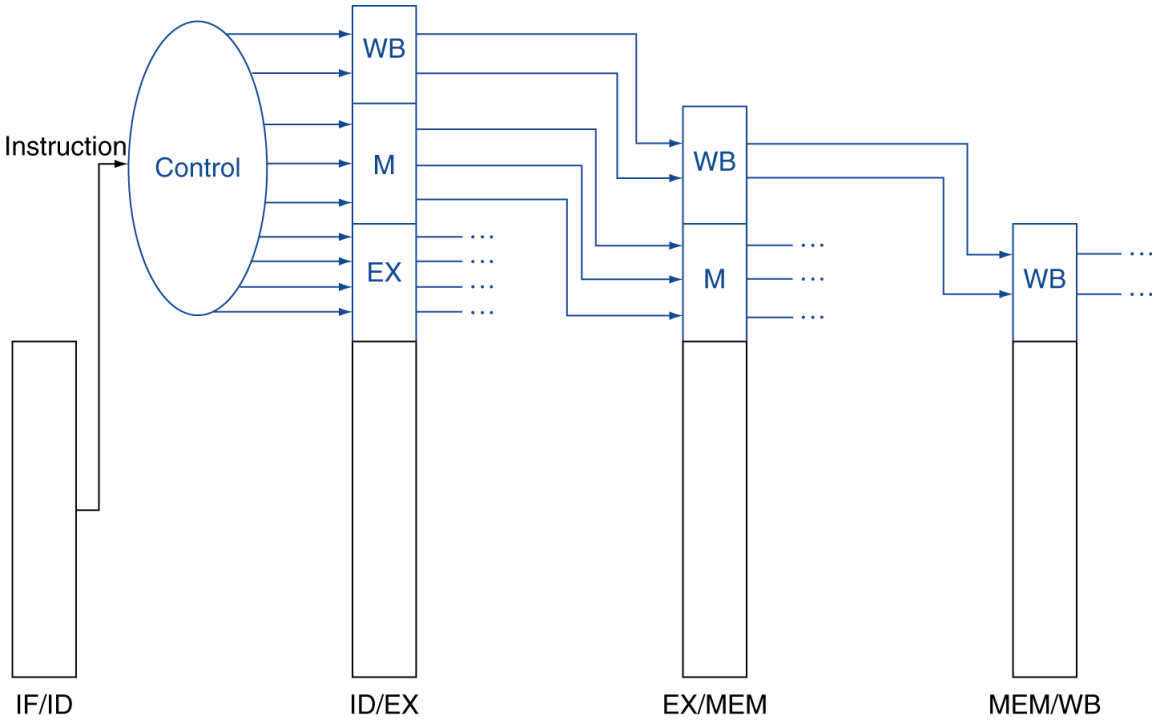
Pipelined Control (Simplified)



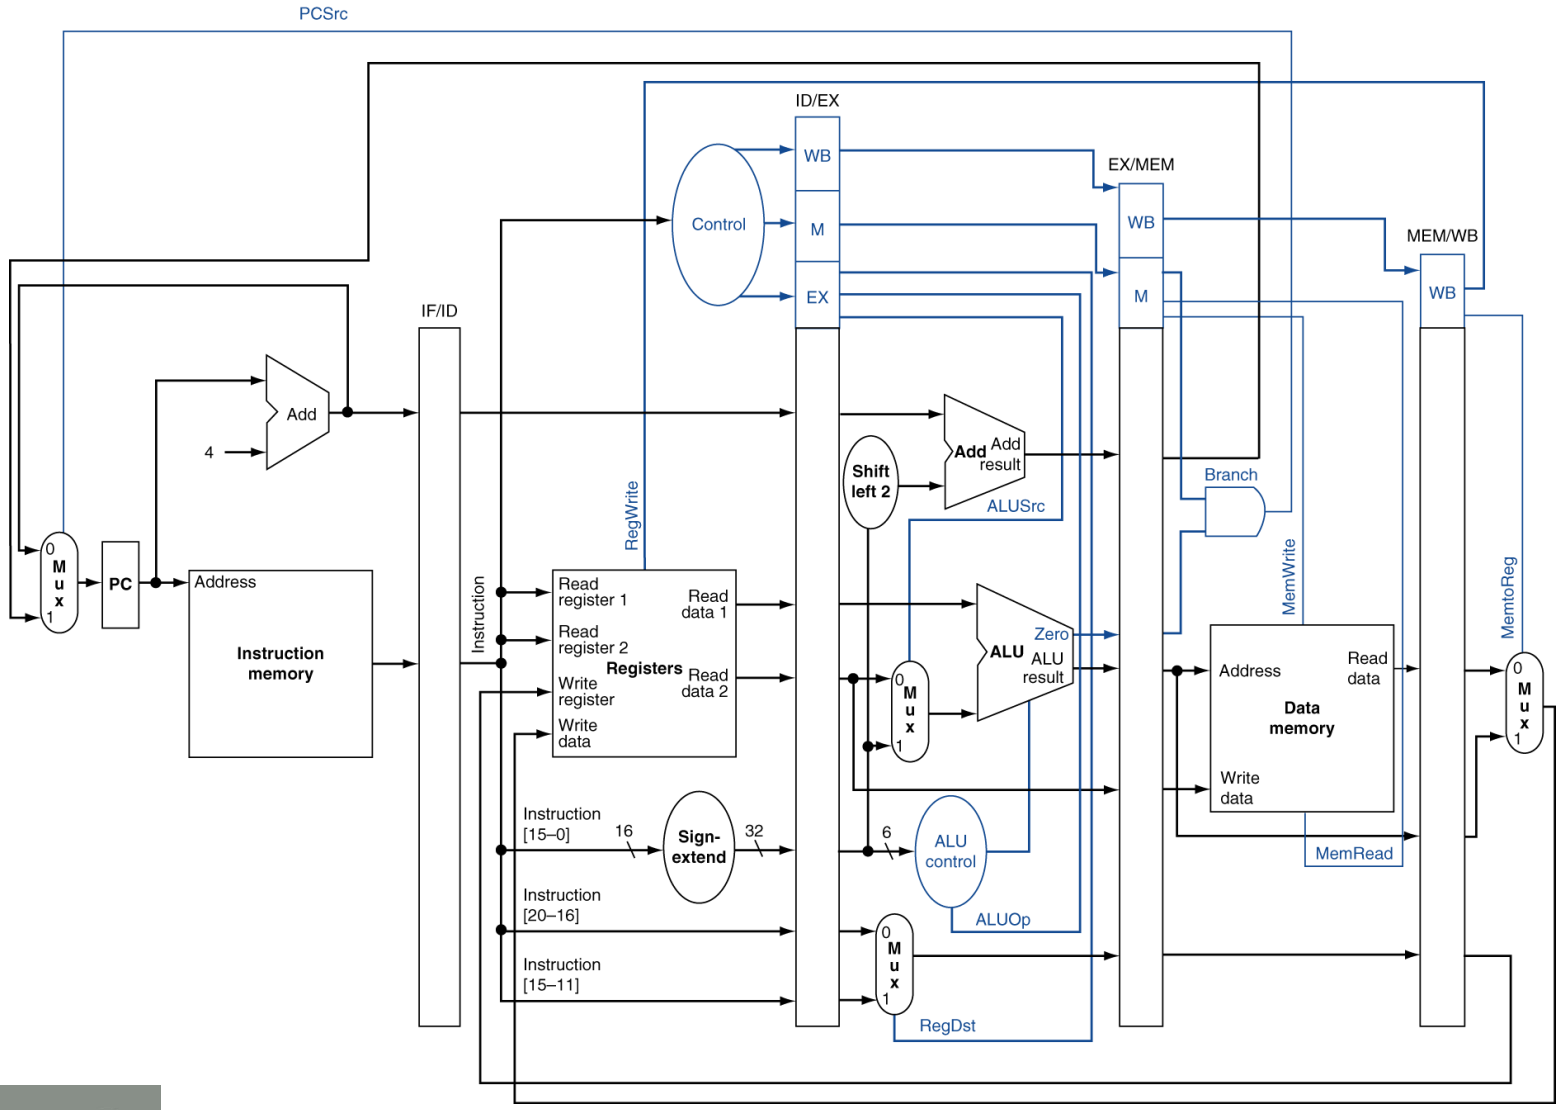
Need to generate control signals at the right time.

Pipelined Control

- Control signals derived from instruction
  - As in single-cycle implementation



Pipelined Control



Handling Hazards: Tools we have

- 1. Stalling: Bubbles, possibly fillable
- 2. Forwarding
- and occasionally additional hardware

Data Hazards in ALU Instructions

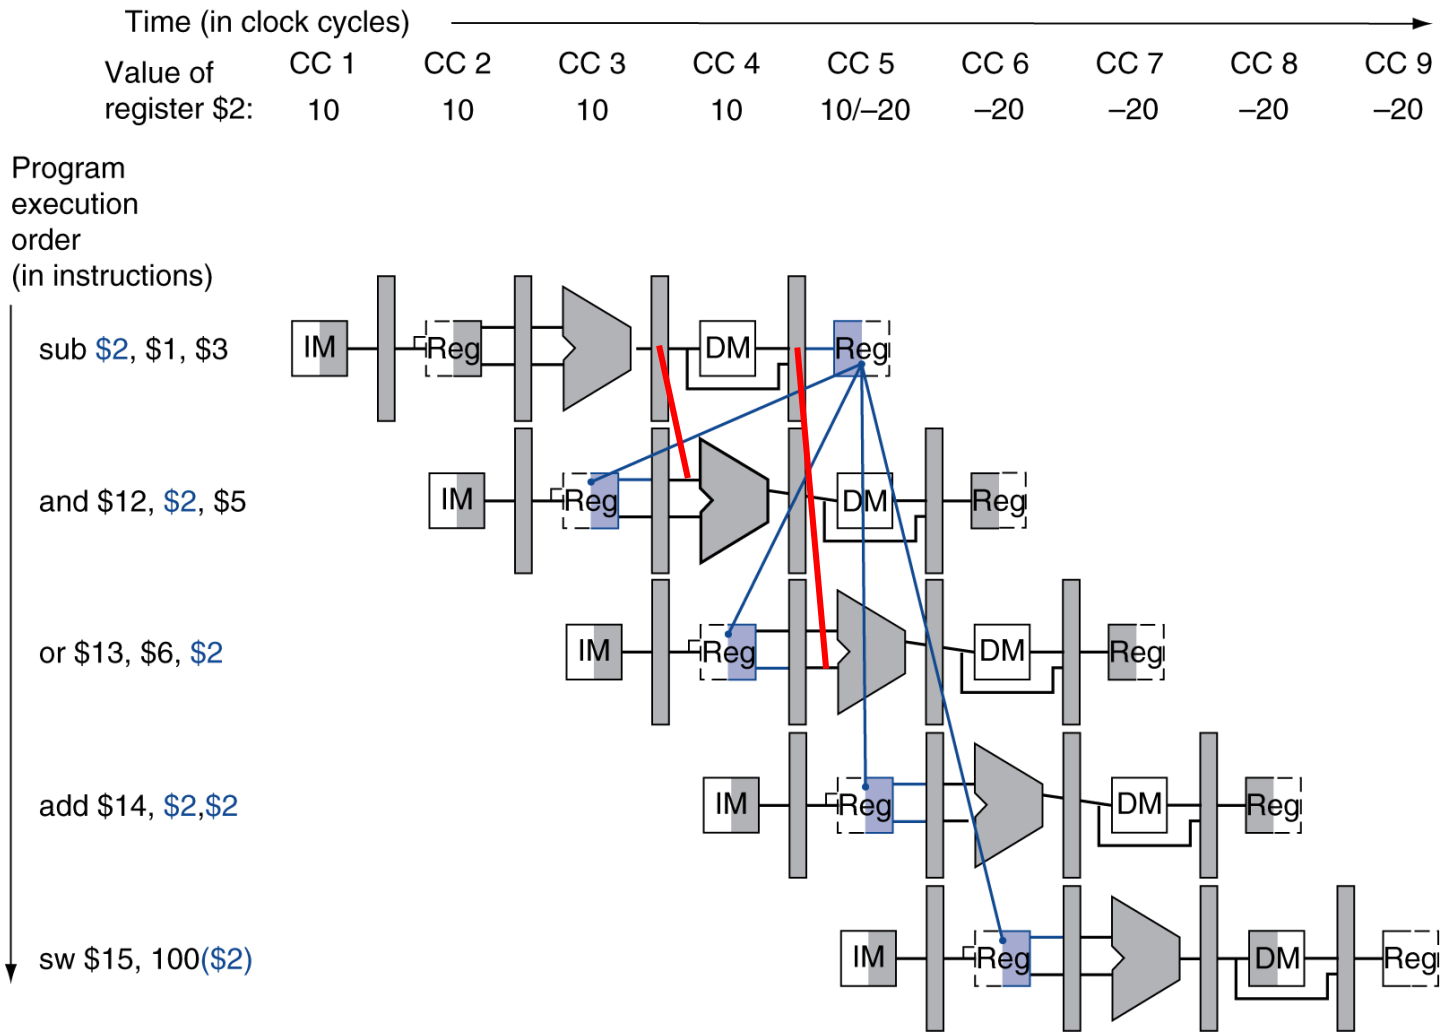
- Consider this sequence:

```
sub $2, $1,$3
and $12,$2,$5
or  $13,$6,$2
add $14,$2,$2
sw  $15,100($2)
```

- We can resolve hazards with forwarding
  - How do we detect when to forward?

Next 9 slides: Detect when a hazard is present (Logic).
Provide lines, MUXes for forwarding (paths).

Dependencies & Forwarding



Blue: dependencies, Red: forwarding

Detecting the Need to Forward

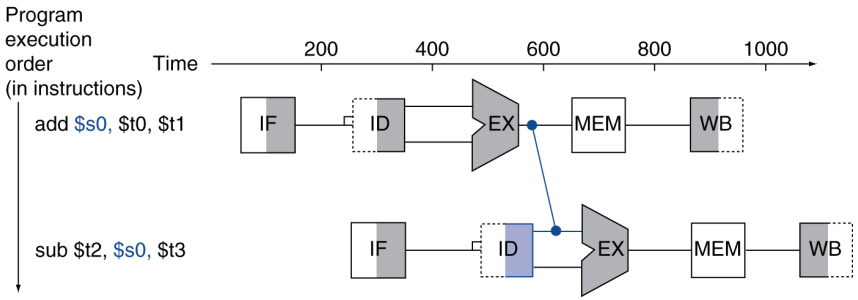
- Pass register numbers along pipeline
  - e.g., ID/EX.RegisterRs = register number for Rs sitting in ID/EX pipeline register
- ALU operand register numbers in EX stage are given by
  - ID/EX.RegisterRs, ID/EX.RegisterRt
- Data hazards when
  - 1a. EX/MEM.RegisterRd = ID/EX.RegisterRs
  - 1b. EX/MEM.RegisterRd = ID/EX.RegisterRt
  - 2a. MEM/WB.RegisterRd = ID/EX.RegisterRs
  - 2b. MEM/WB.RegisterRd = ID/EX.RegisterRt

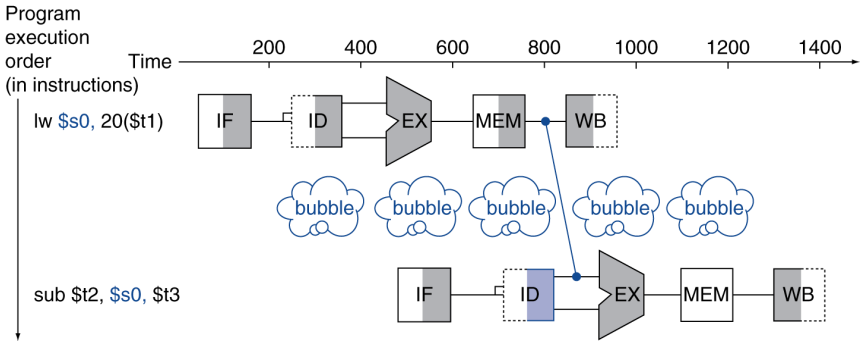
Fwd from EX/MEM pipeline reg

Fwd from MEM/WB pipeline reg

Logical equality not assignment!

Detecting the Need to Forward





- (i) Data hazards when
  - 1a. EX/MEM.RegisterRd = ID/EX.RegisterRs
  - 1b. EX/MEM.RegisterRd = ID/EX.RegisterRt
  - 2a. MEM/WB.RegisterRd = ID/EX.RegisterRs
  - 2b. MEM/WB.RegisterRd = ID/EX.RegisterRt

Fwd from EX/MEM pipeline reg

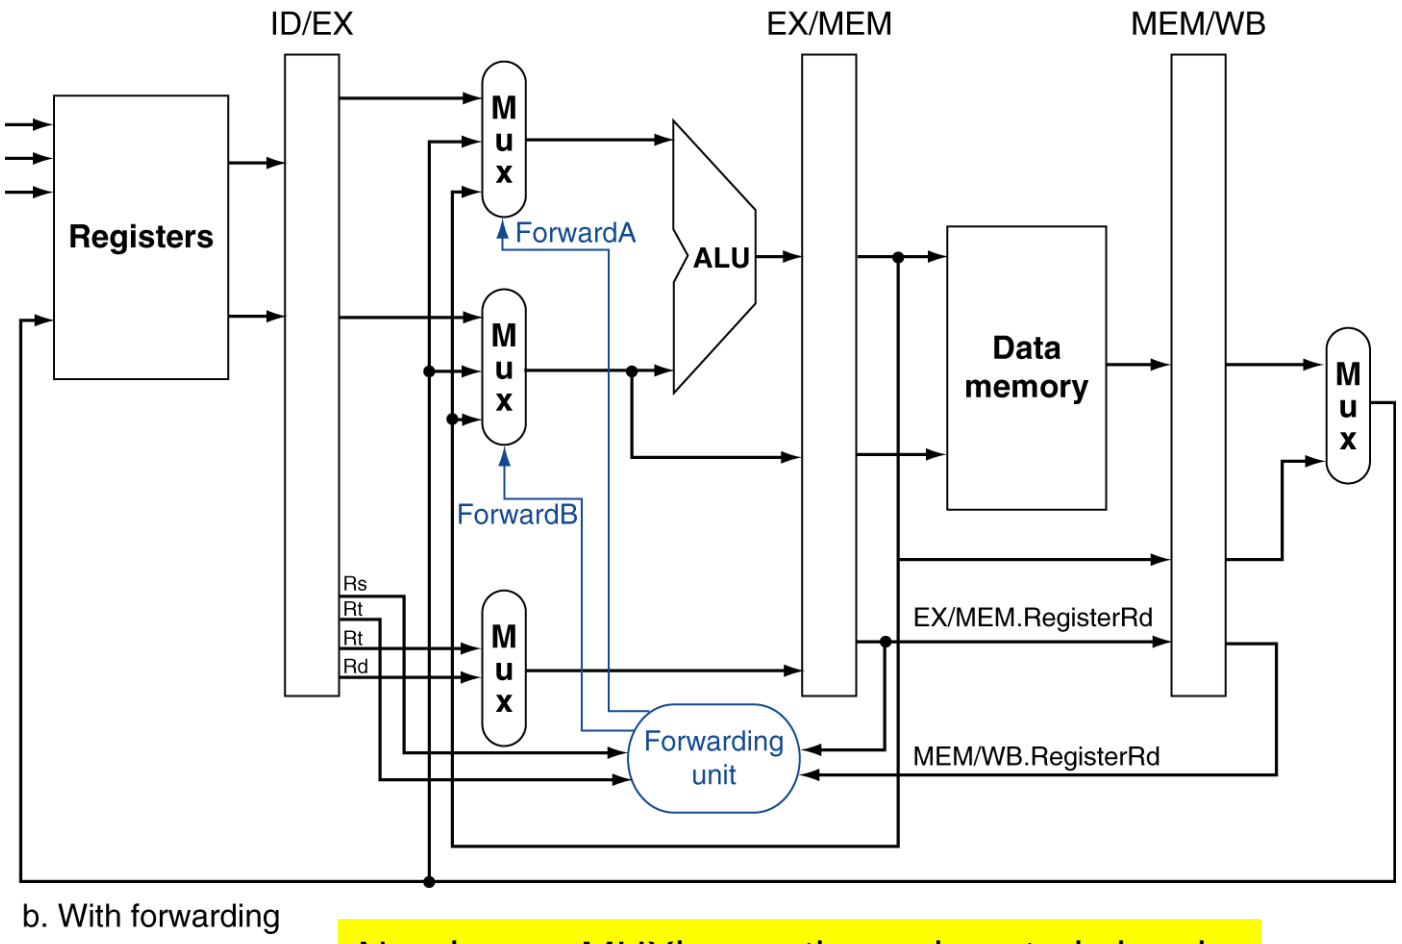
Fwd from MEM/WB pipeline reg

Logical equality not assignment!

Detecting the Need to Forward

- (ii) But only if forwarding instruction will write to a register!
  - EX/MEM.RegWrite, MEM/WB.RegWrite
- (iii) And only if Rd for that instruction is not $zero
  - EX/MEM.RegisterRd ≠ 0, MEM/WB.RegisterRd ≠ 0

Forwarding Paths



b. With forwarding

Need more MUXing: paths and control signals (ForwardA and ForwardB: 2 lines)

Forwarding Conditions

- EX hazard
  - if (EX/MEM.RegWrite and (EX/MEM.RegisterRd ≠ 0)
    and (EX/MEM.RegisterRd = ID/EX.RegisterRs))
    ForwardA = 10
  - if (EX/MEM.RegWrite and (EX/MEM.RegisterRd ≠ 0)
    and (EX/MEM.RegisterRd = ID/EX.RegisterRt))
    ForwardB = 10
- MEM hazard
  - if (MEM/WB.RegWrite and (MEM/WB.RegisterRd ≠ 0)
    and (MEM/WB.RegisterRd = ID/EX.RegisterRs))
    ForwardA = 01
  - if (MEM/WB.RegWrite and (MEM/WB.RegisterRd ≠ 0)
    and (MEM/WB.RegisterRd = ID/EX.RegisterRt))
    ForwardB = 01

But ..

Double Data Hazard

- Consider the sequence:

```
add $1,$1,$2
add $1,$1,$3
add $1,$1,$4
```

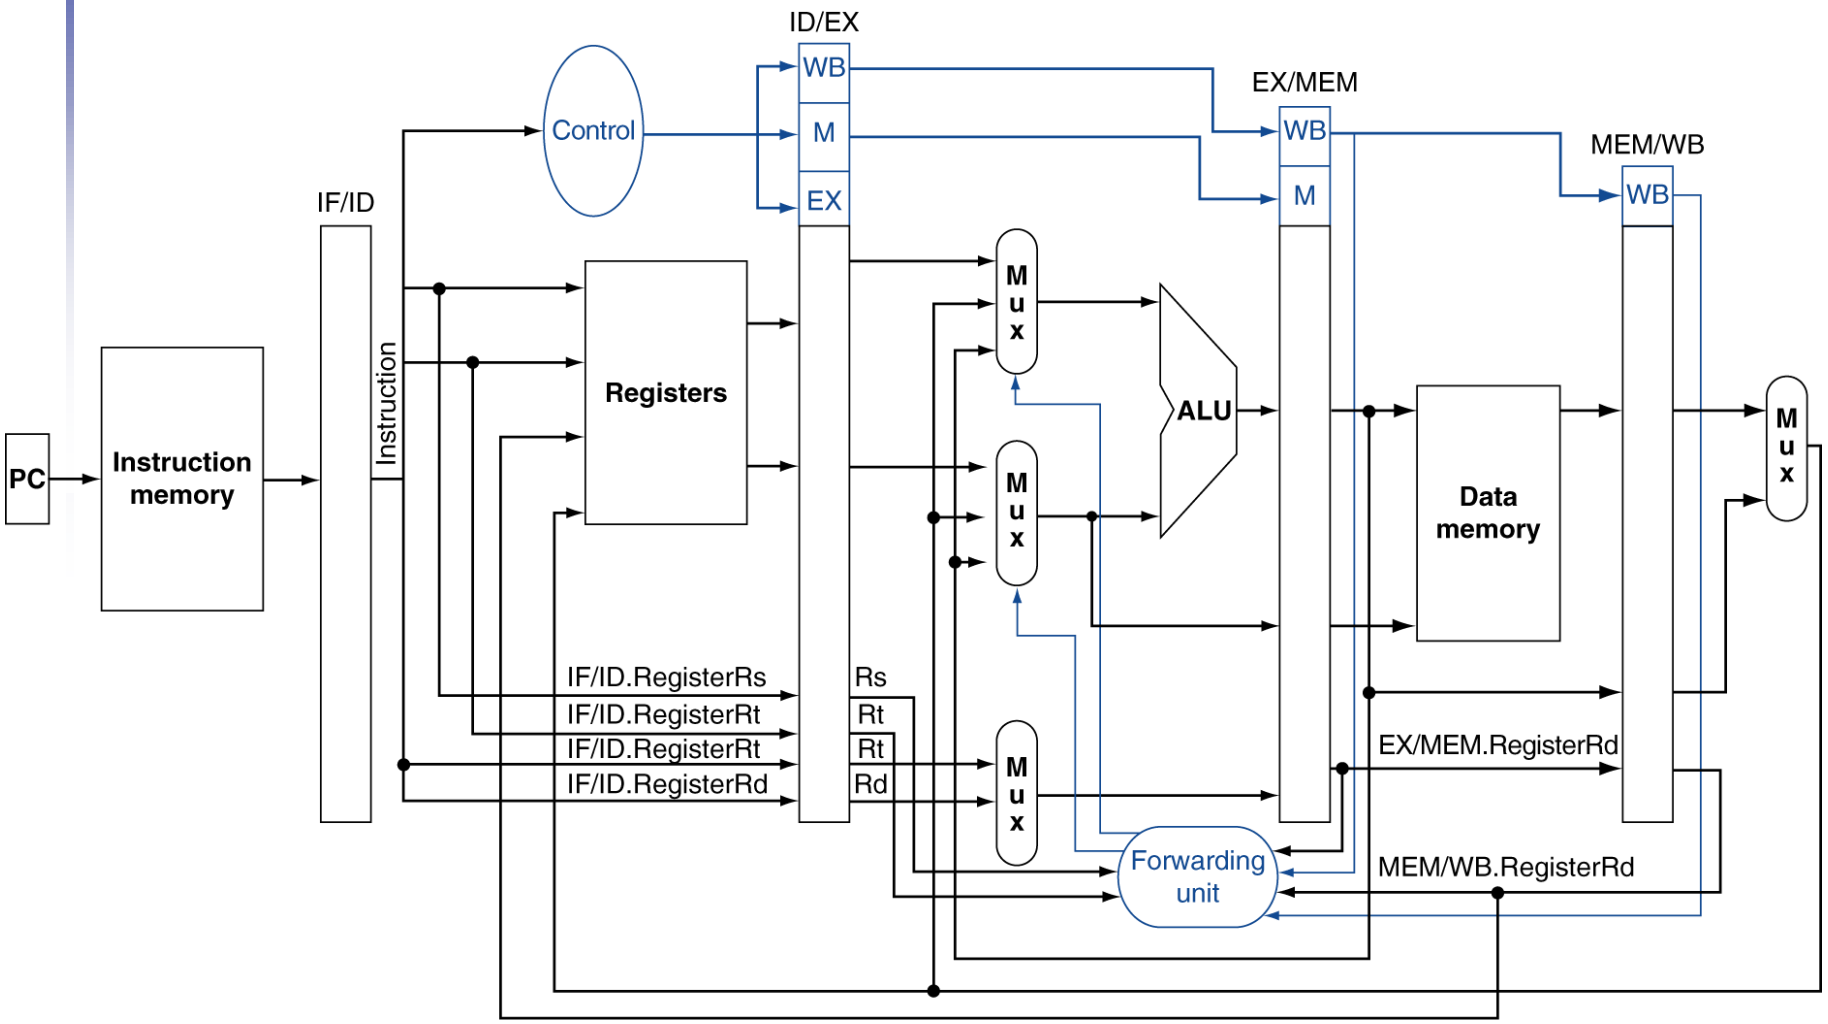
- Both hazards occur
  - Want to use the most recent
- Revise MEM hazard condition
  - Only fwd if EX hazard condition isn't true

Revised Forwarding Condition

- MEM hazard
  - if (MEM/WB.RegWrite and (MEM/WB.RegisterRd ≠ 0)
    and not (EX/MEM.RegWrite and (EX/MEM.RegisterRd ≠ 0)
    and (EX/MEM.RegisterRd = ID/EX.RegisterRs))
    and (MEM/WB.RegisterRd = ID/EX.RegisterRs))
    ForwardA = 01
  - if (MEM/WB.RegWrite and (MEM/WB.RegisterRd ≠ 0)
    and not (EX/MEM.RegWrite and (EX/MEM.RegisterRd ≠ 0)
    and (EX/MEM.RegisterRd = ID/EX.RegisterRt))
    and (MEM/WB.RegisterRd = ID/EX.RegisterRt))
    ForwardB = 01

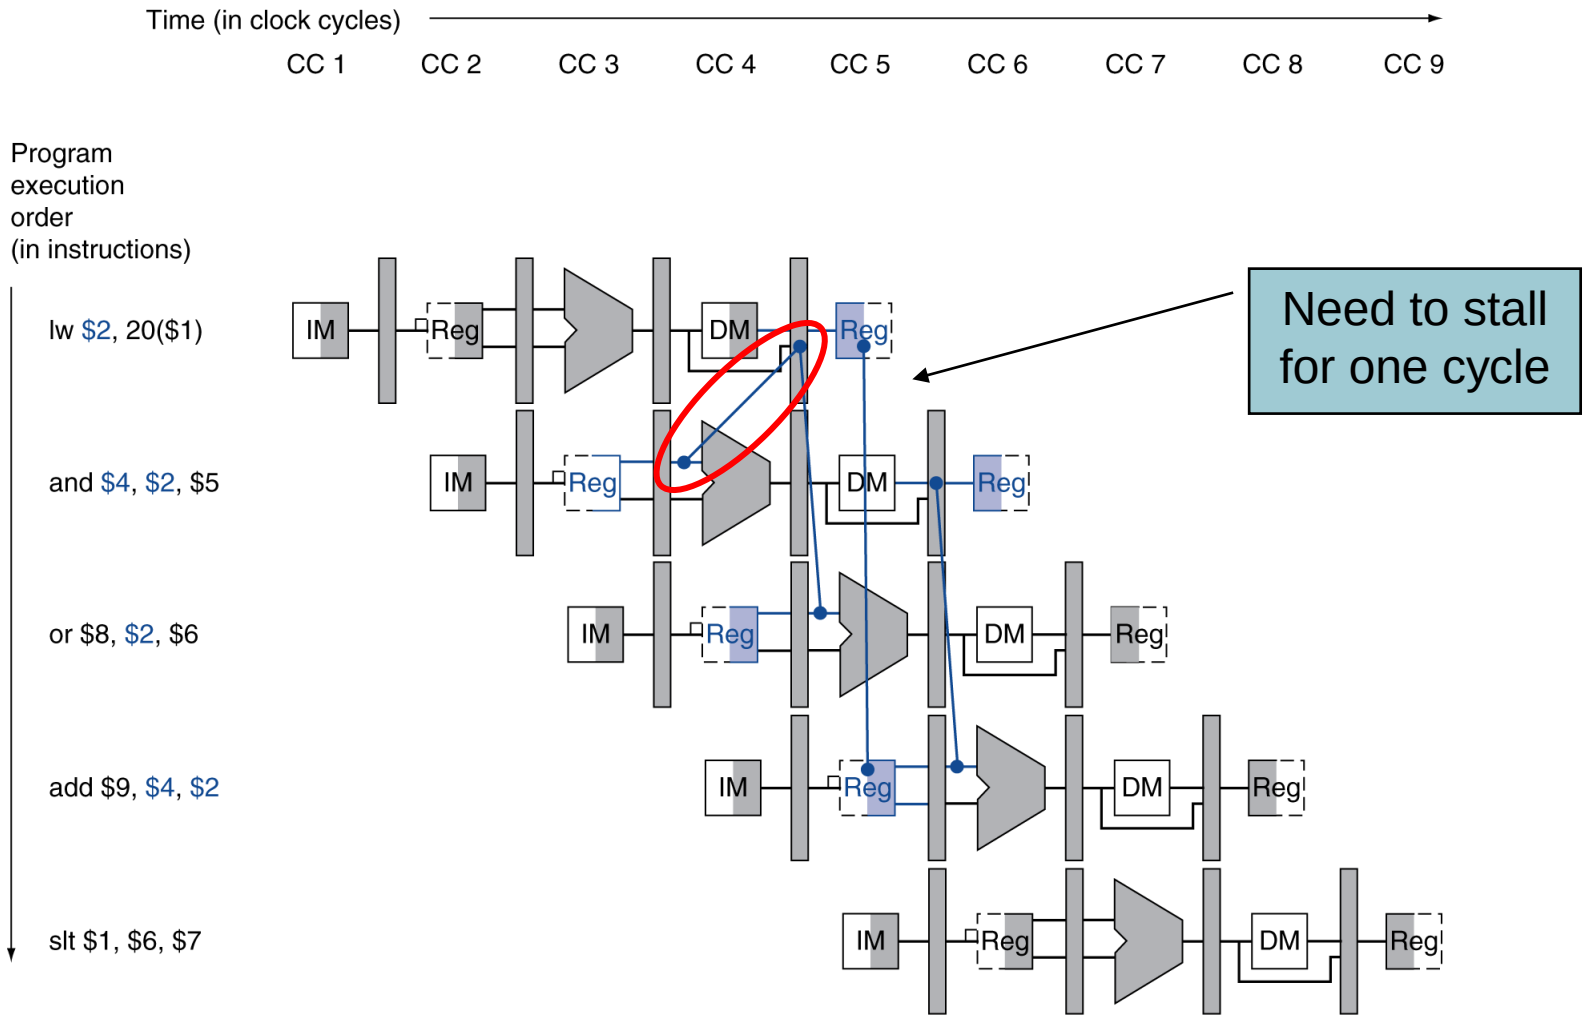
Detect when a hazard is present (Logic). This is the logic

Datapath with Forwarding



Load-Use Data Hazard

Next 5 slides: Detect when this hazard is present (Logic). Stall pipeline.



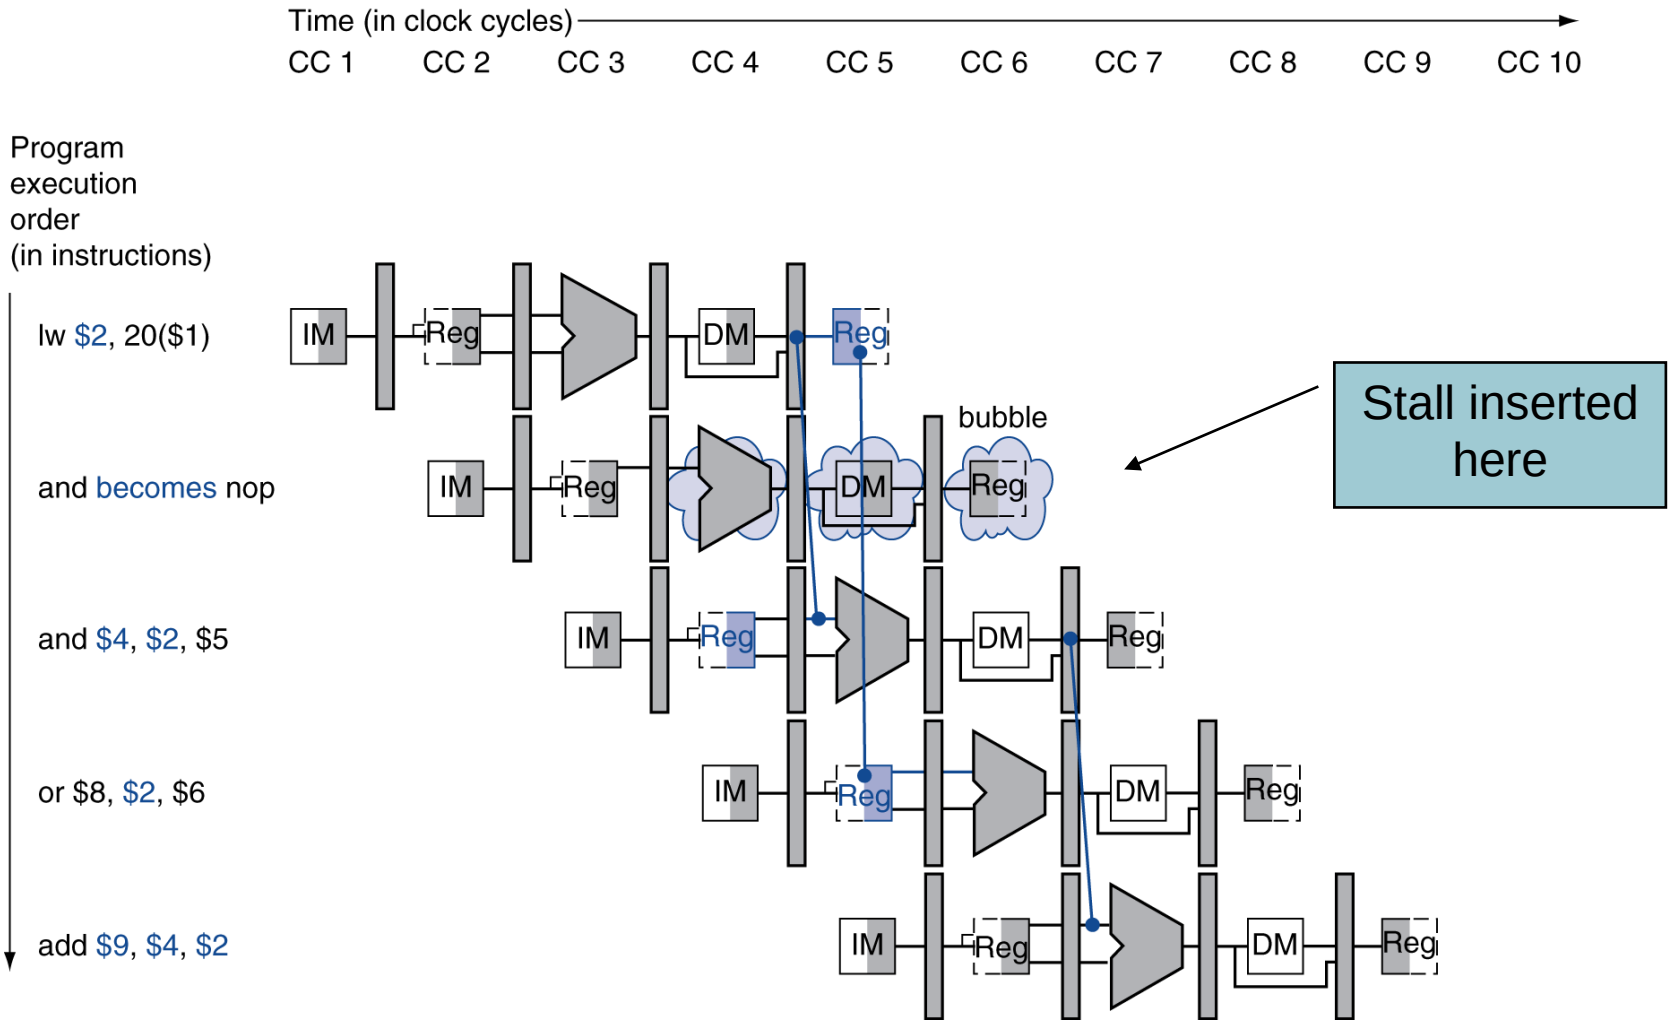
Load-Use Hazard Detection

- Check when using instruction is decoded in ID stage
- ALU operand register numbers in ID stage are given by
  - IF/ID.RegisterRs, IF/ID.RegisterRt
- Load-use hazard when
  - ID/EX.MemRead and
    ((ID/EX.RegisterRt = IF/ID.RegisterRs) or
    (ID/EX.RegisterRt = IF/ID.RegisterRt))
- If detected, stall and insert bubble

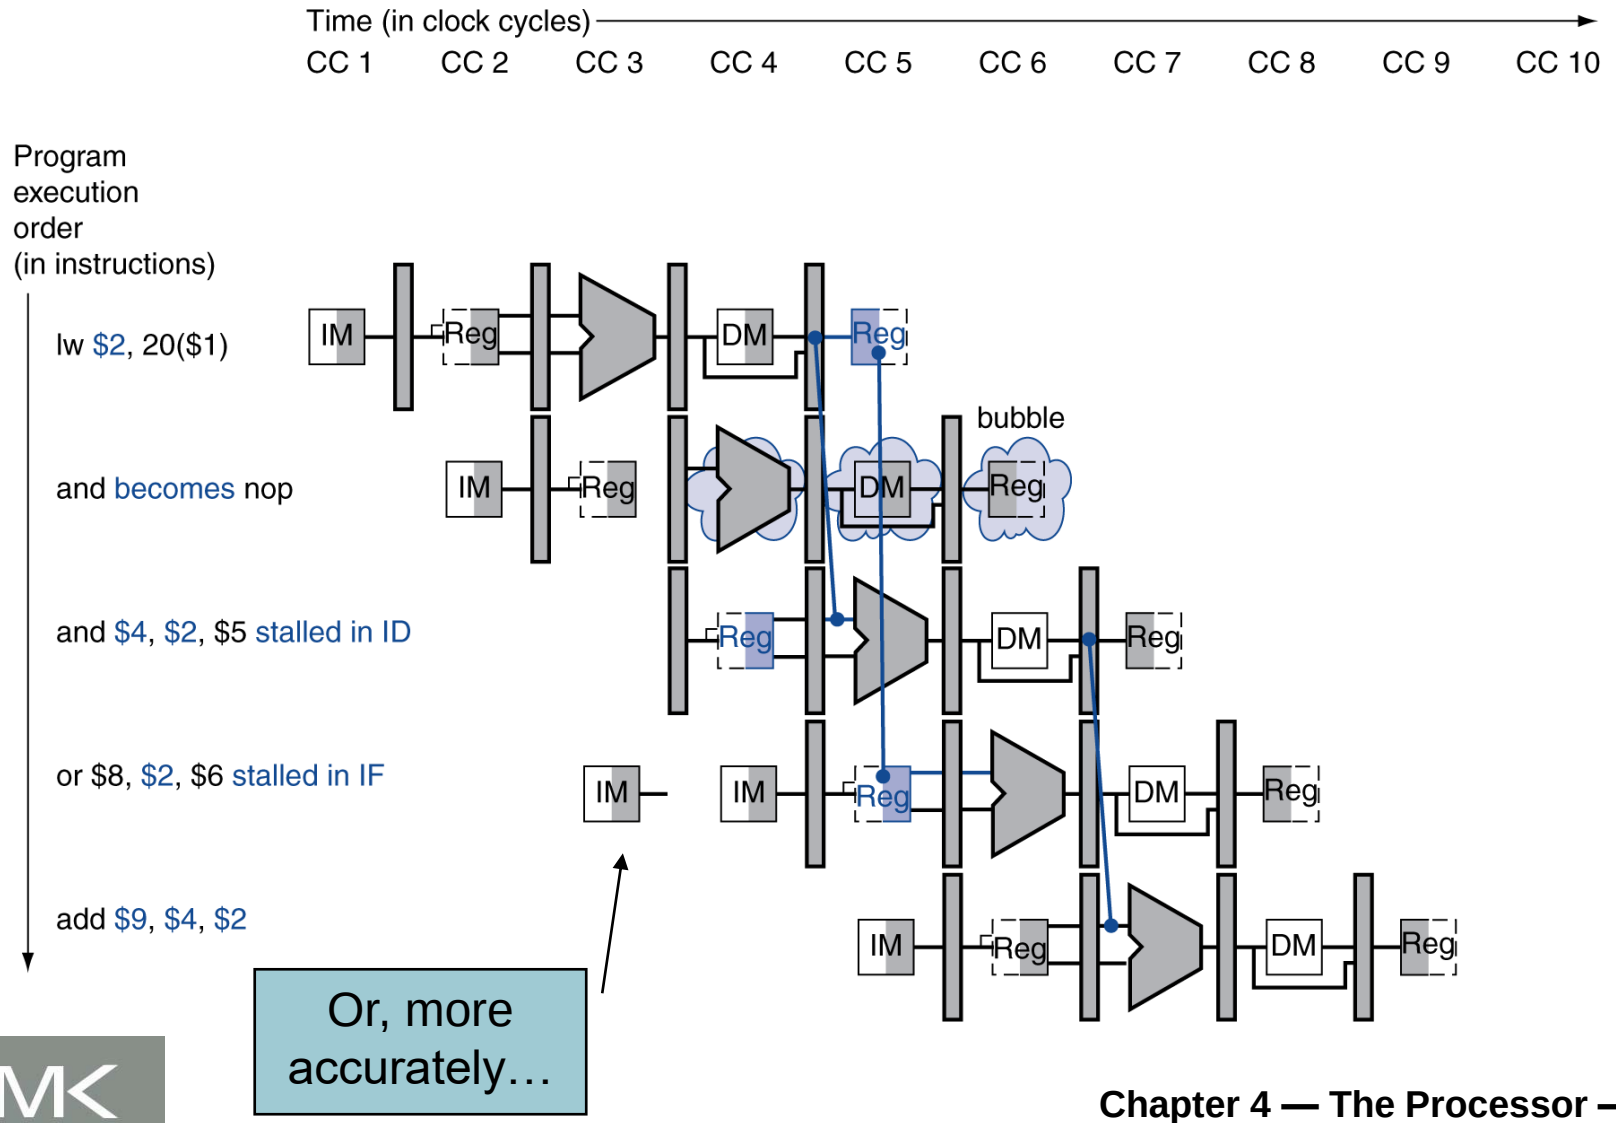
How to Stall the Pipeline

- Force control values in ID/EX register to 0
  - EX, MEM and WB do nop (no-operation)
- Prevent update of PC and IF/ID register
  - Using instruction is decoded again
  - Following instruction is fetched again
  - 1-cycle stall allows MEM to read data for lw
    - Can subsequently forward to EX stage

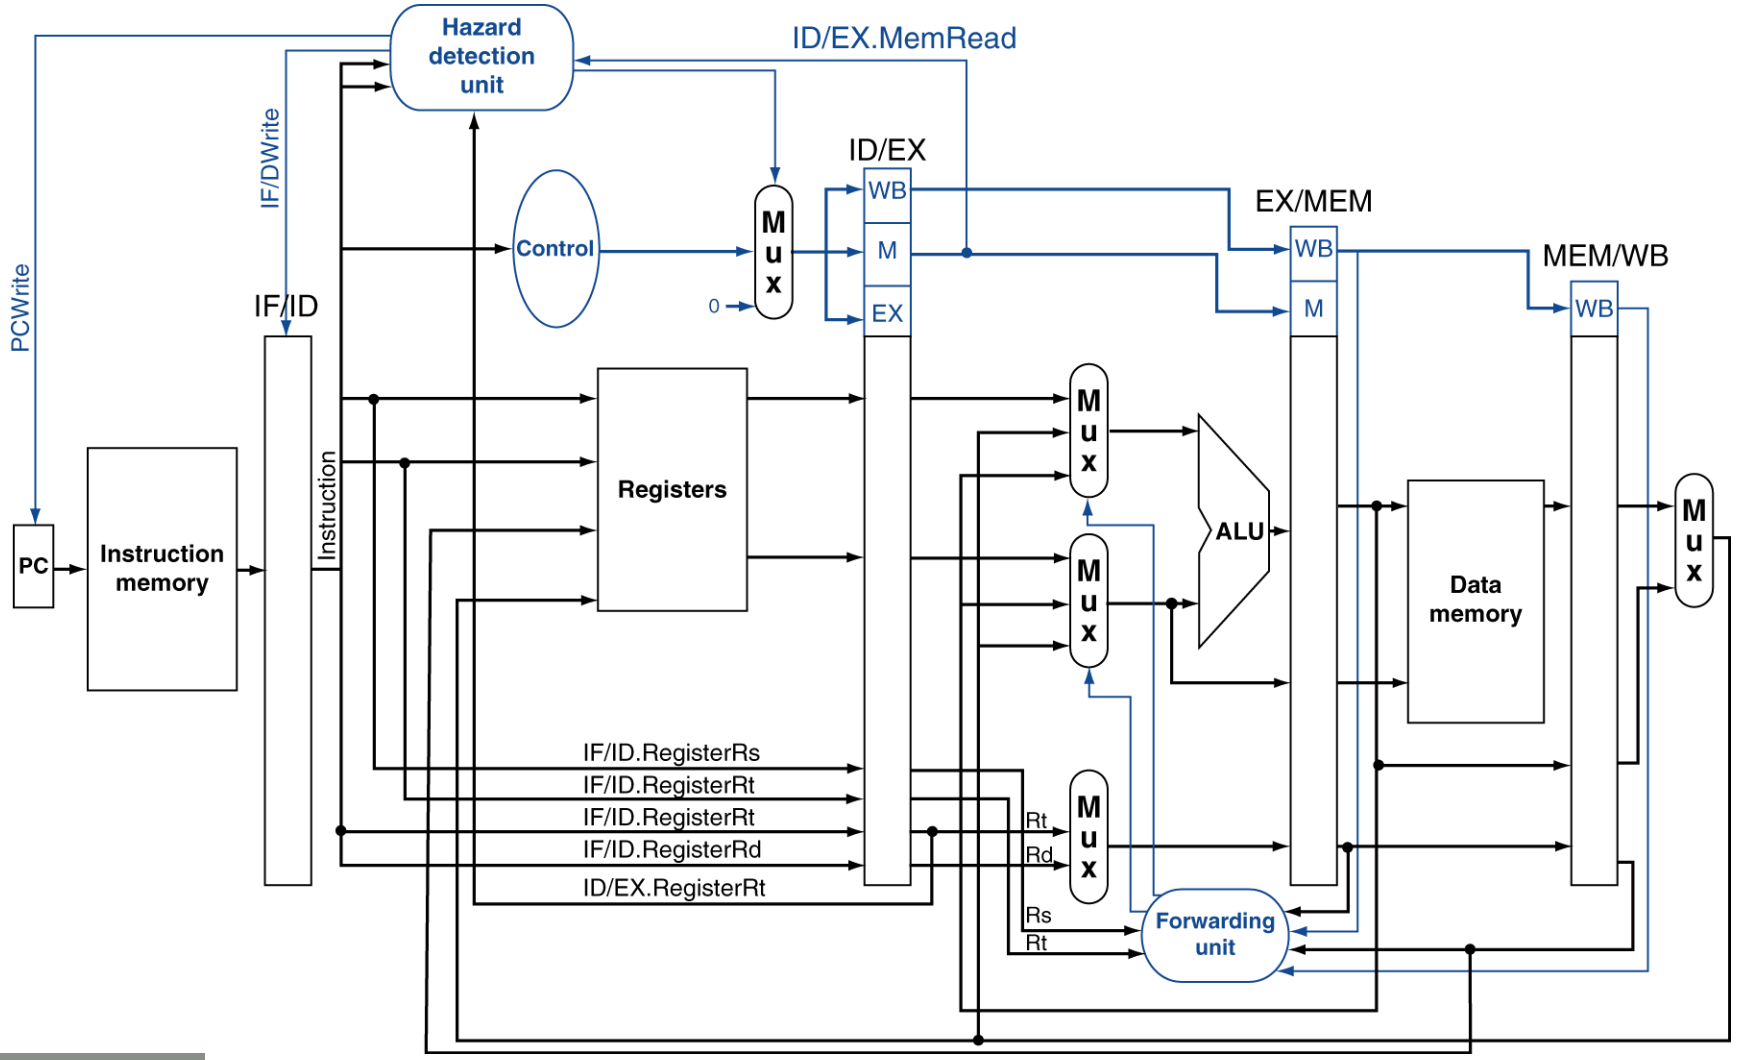
Stall/Bubble in the Pipeline



Stall/Bubble in the Pipeline



Datapath with Hazard Detection



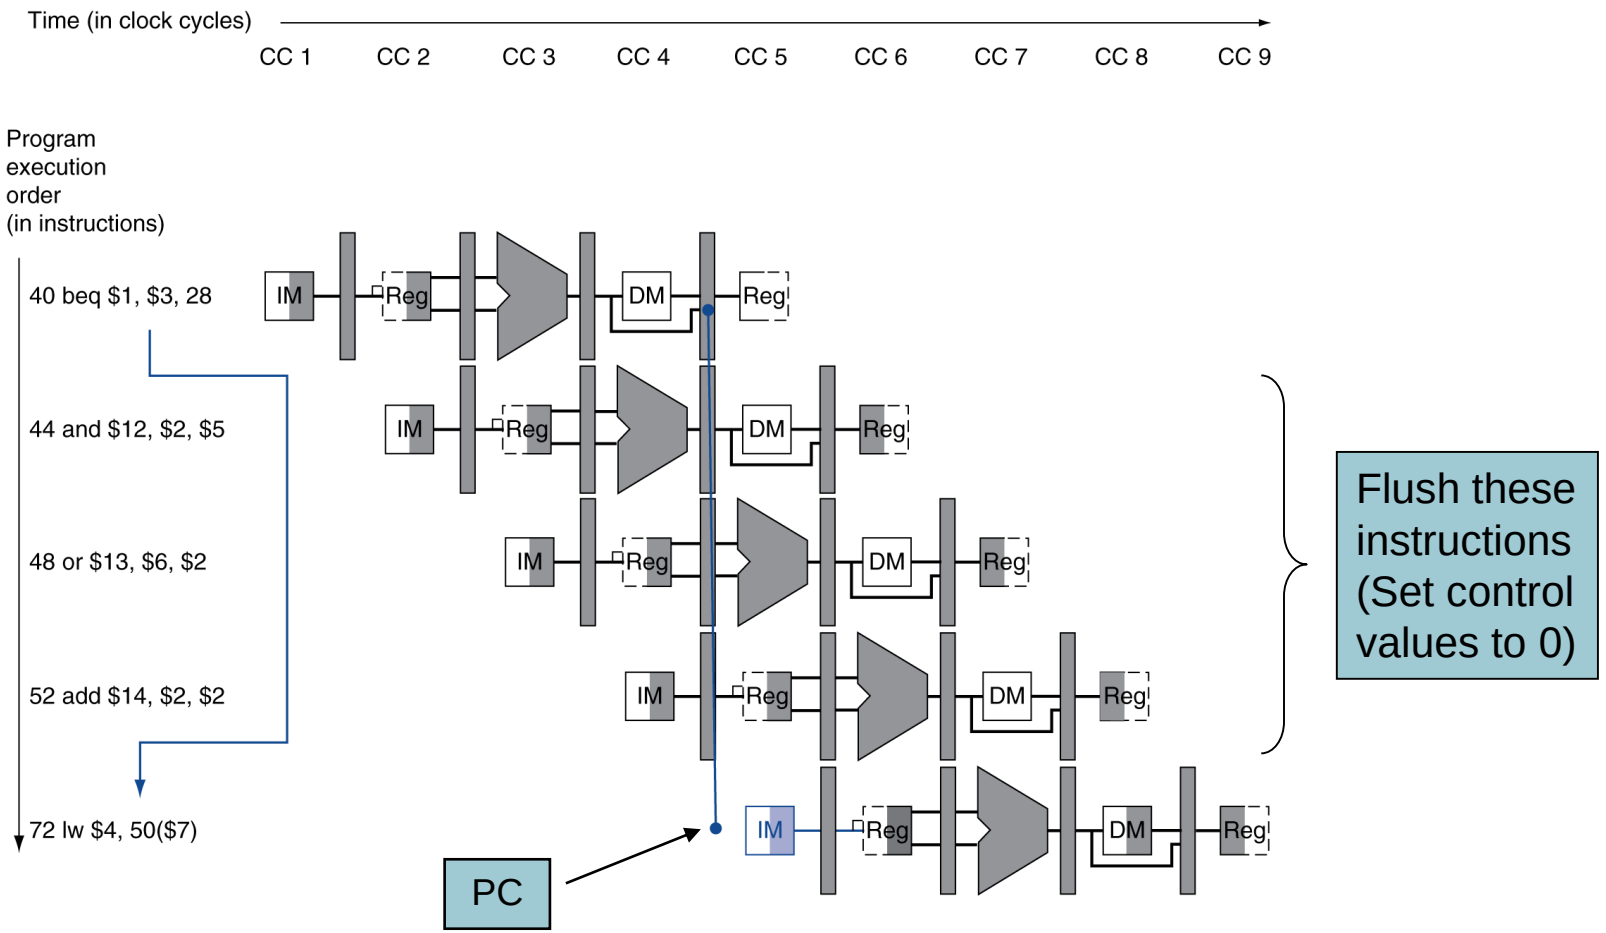
Stalls and Performance

The BIG Picture

- Stalls reduce performance
  - But are required to get correct results
- Compiler can arrange code to avoid hazards and stalls
  - Requires knowledge of the pipeline structure

Branch Hazards

- If branch outcome determined in MEM

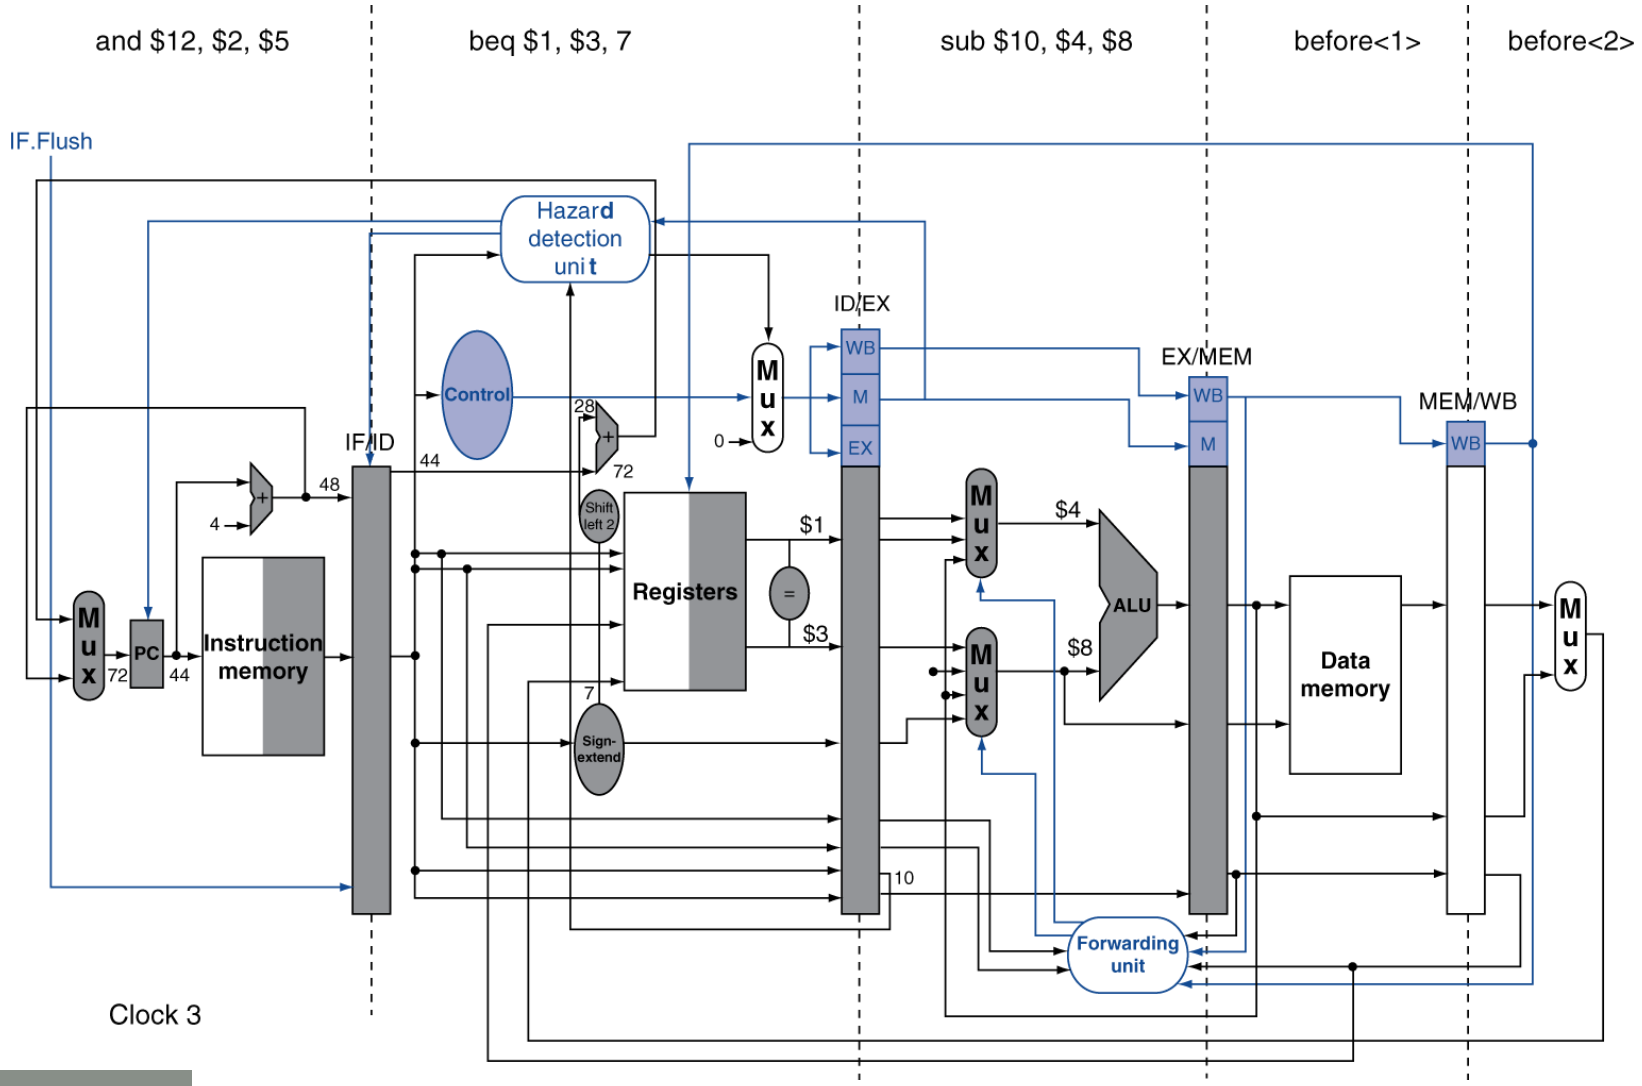


Reducing Branch Delay

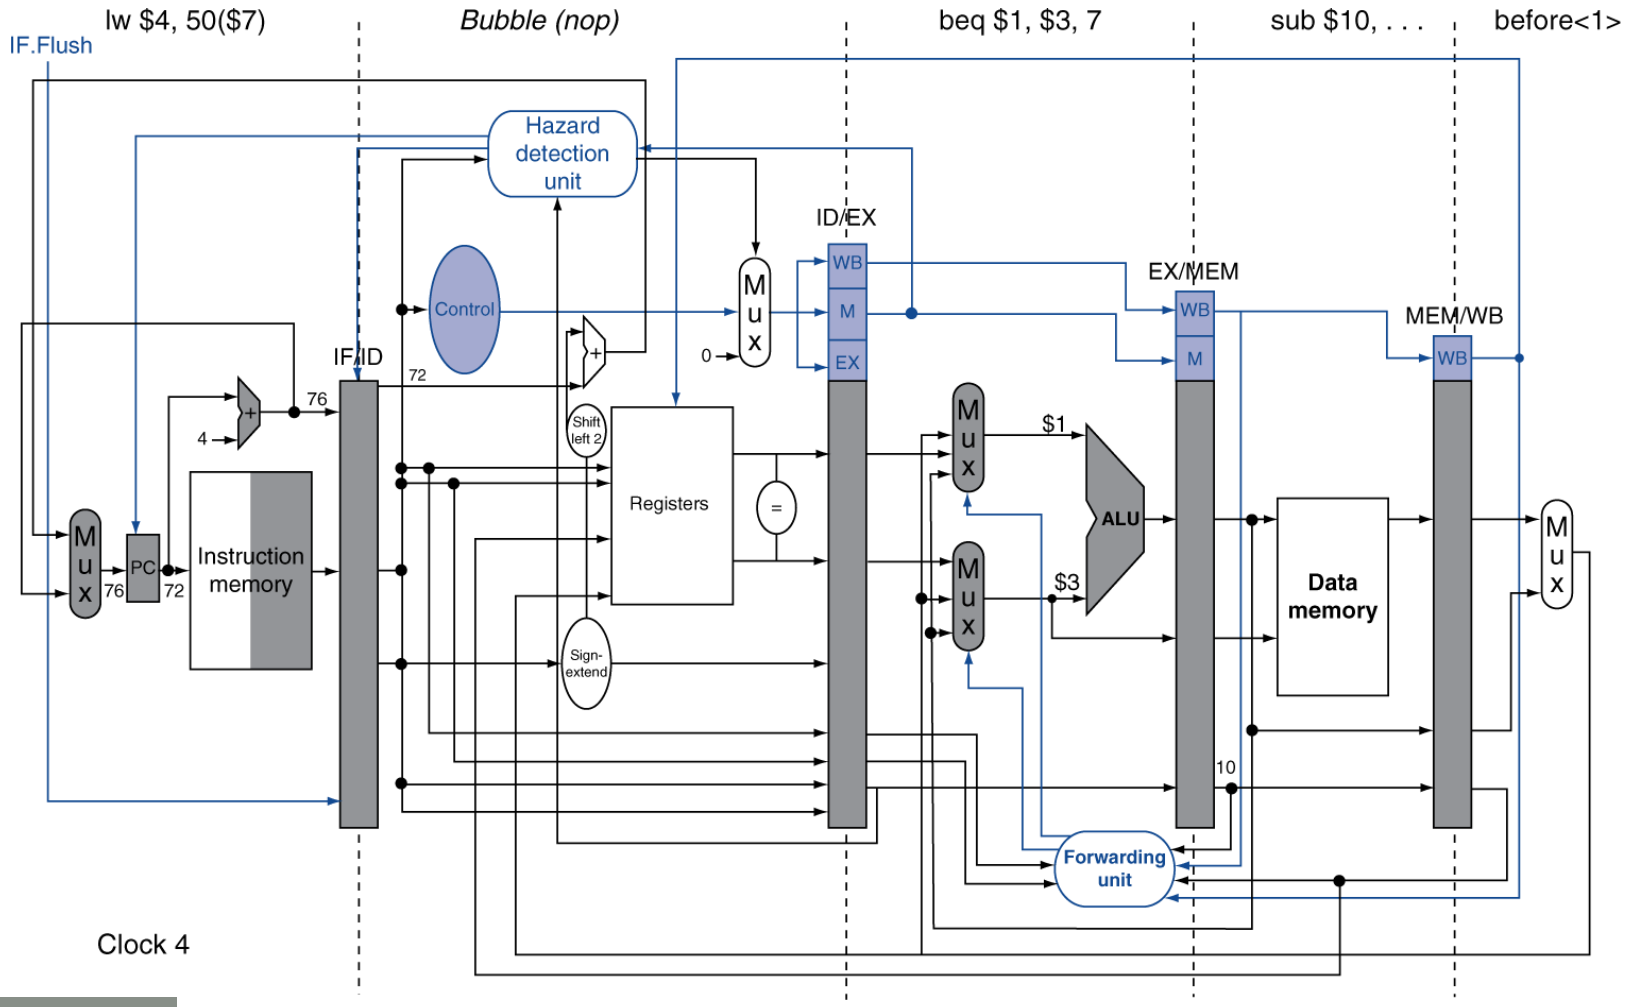
- Move hardware to determine outcome to ID stage
  - Target address adder
  - Register comparator
- Example: branch taken

```
36:  sub  $10, $4, $8
40:  beq  $1,  $3, 7
44:  and  $12, $2, $5
48:  or   $13, $2, $6
52:  add  $14, $4, $2
56:  slt  $15, $6, $7
     ...
72:  lw   $4, 50($7)
```

Example: Branch Taken

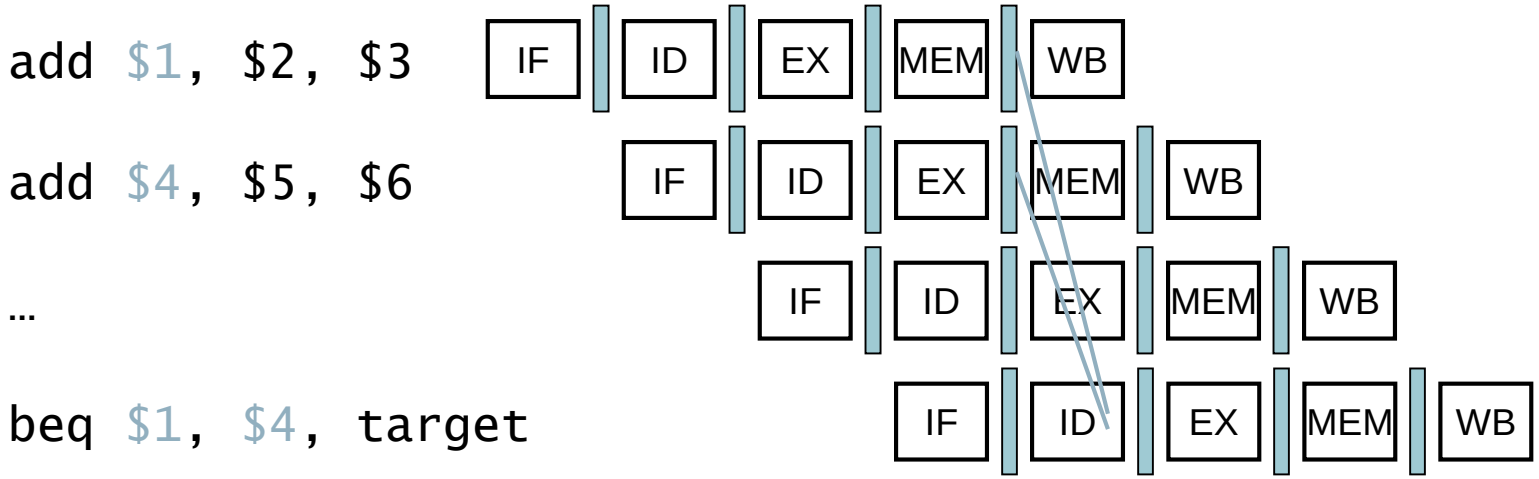


Example: Branch Taken



Data Hazards for Branches

- If a comparison register is a destination of 2nd or 3rd preceding ALU instruction

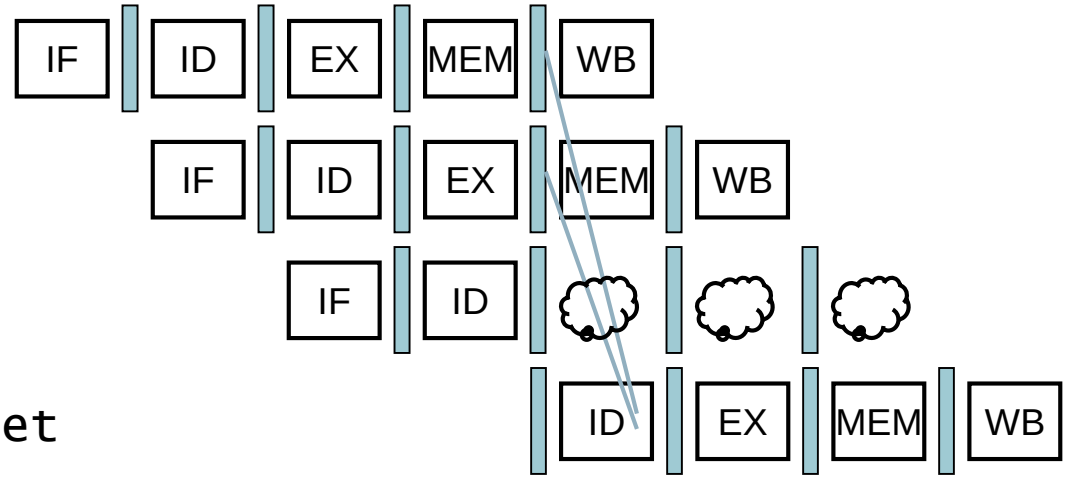


- Can resolve using forwarding

Data Hazards for Branches

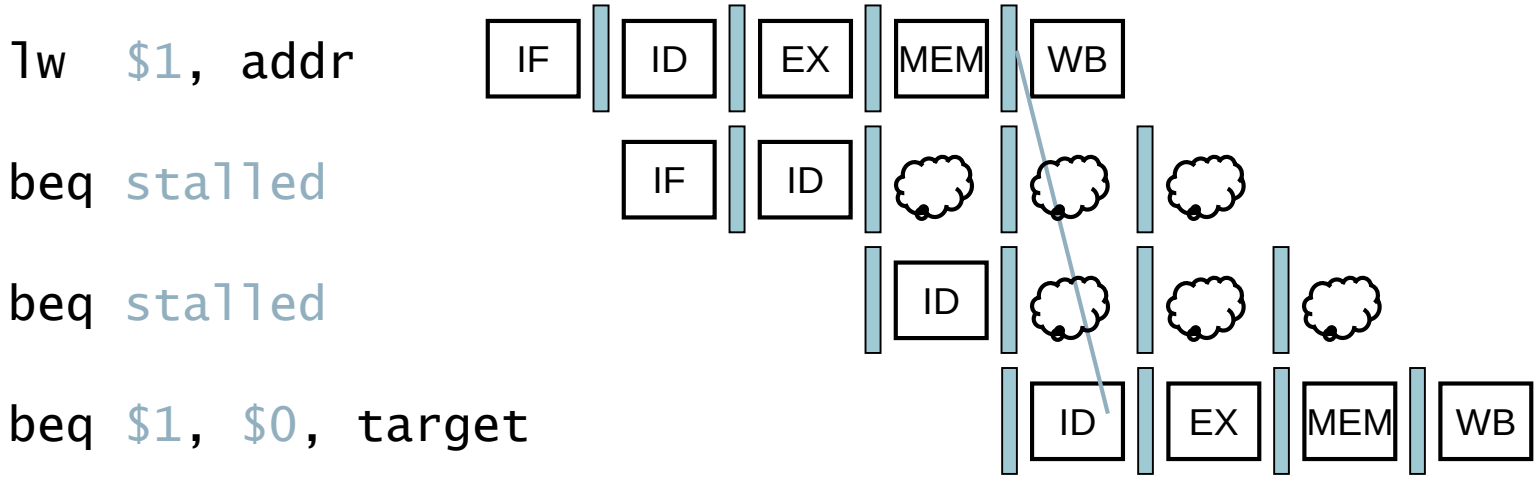
- If a comparison register is a destination of preceding ALU instruction or 2nd preceding load instruction
  - Need 1 stall cycle

```
lw  $1, addr
add $4, $5, $6
beq stalled
beq $1, $4, target
```



Data Hazards for Branches

- If a comparison register is a destination of immediately preceding load instruction
  - Need 2 stall cycles



Dynamic Branch Prediction

- In deeper and superscalar pipelines, branch penalty is more significant
- Use dynamic prediction
  - Branch prediction buffer (aka branch history table)
  - Indexed by recent branch instruction addresses
  - Stores outcome (taken/not taken)
  - To execute a branch
    - Check table, expect the same outcome
    - Start fetching from fall-through or target
    - If wrong, flush pipeline and flip prediction

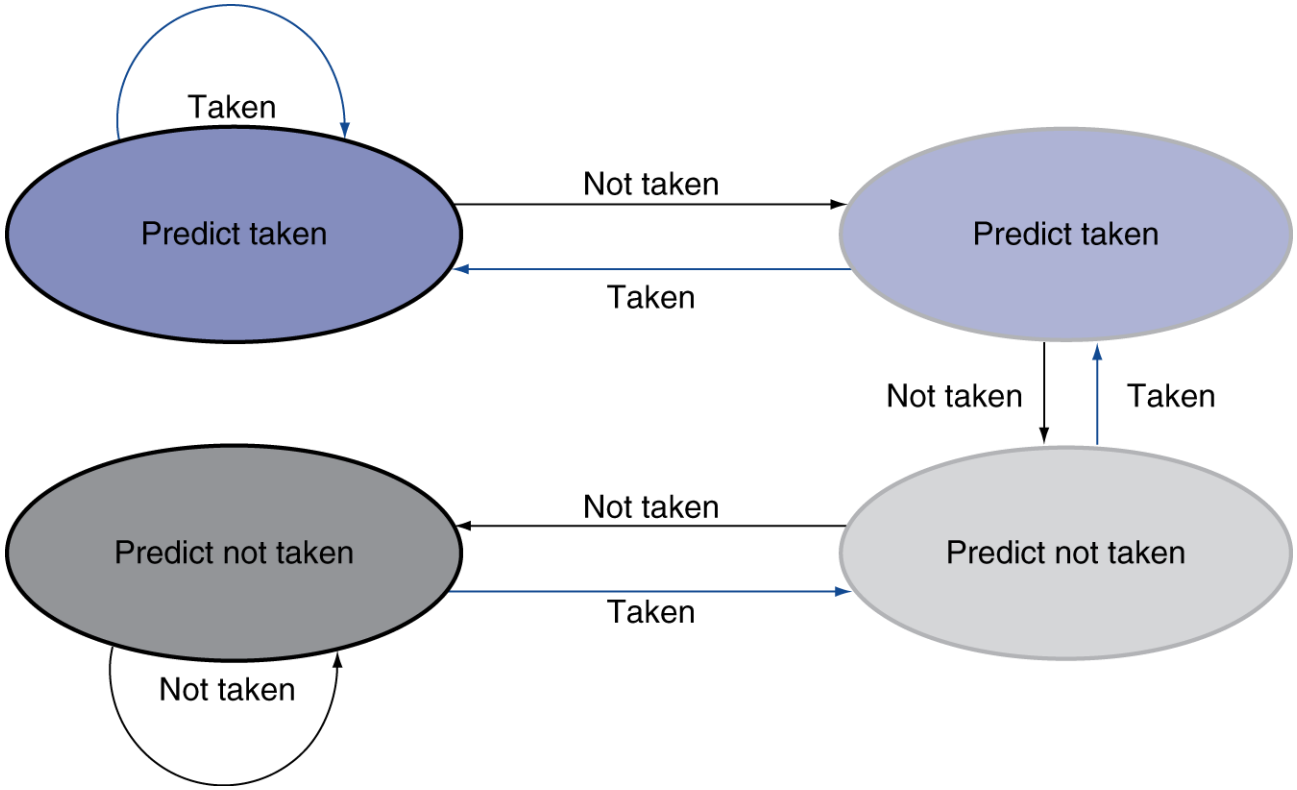
1-Bit Predictor: Shortcoming

- Inner loop branches mispredicted twice!

  - Mispredict as taken on last iteration of inner loop
  - Then mispredict as not taken on first iteration of inner loop next time around

2-Bit Predictor

- Only change prediction on two successive mispredictions



Calculating the Branch Target

- Even with predictor, still need to calculate the target address
  - 1-cycle penalty for a taken branch
- Branch target buffer
  - Cache of target addresses
  - Indexed by PC when instruction fetched
    - If hit and instruction is branch predicted taken, can fetch target immediately

Exceptions and Interrupts

- “Unexpected” events requiring change in flow of control
  - Different ISAs use the terms differently
- Exception
  - Arises within the CPU
    - e.g., undefined opcode, overflow, syscall, …
- Interrupt
  - From an external I/O controller
- Dealing with them without sacrificing performance is hard

Handling Exceptions

- In MIPS, exceptions managed by a System Control Coprocessor (CP0)
- Save PC of offending (or interrupted) instruction
  - In MIPS: Exception Program Counter (EPC)
- Save indication of the problem
  - In MIPS: Cause register
  - We'll assume 1-bit
    - 0 for undefined opcode, 1 for overflow
- Jump to handler at 8000 00180

An Alternate Mechanism

- Vectored Interrupts
  - Handler address determined by the cause
- Example:
  - Undefined opcode: C000 0000
  - Overflow: C000 0020
  - …: C000 0040
- Instructions either
  - Deal with the interrupt, or
  - Jump to real handler

Handler Actions

- Read cause, and transfer to relevant handler
- Determine action required
- If restartable
  - Take corrective action
  - use EPC to return to program
- Otherwise
  - Terminate program
  - Report error using EPC, cause, …

Exceptions in a Pipeline

- Another form of control hazard
- Consider overflow on add in EX stage

  `add $1, $2, $1`

  - Prevent $1 from being clobbered
  - Complete previous instructions
  - Flush add and subsequent instructions
  - Set Cause and EPC register values
  - Transfer control to handler
- Similar to mispredicted branch
  - Use much of the same hardware
